STABILITY AND INSTABILITY OF EXTREME REISSNER-NORDSTRÖM BLACK HOLE SPACETIMES FOR LINEAR SCALAR PERTURBATIONS II

STEFANOS ARETAKIS*

Abstract. This paper contains the second part of a two-part series on the stability and instability of extreme Reissner-Nordström spacetimes for linear scalar perturbations. We continue our study of solutions to the linear wave equation $\Box_g\psi=0$ on a suitable globally hyperbolic subset of such a spacetime, arising from regular initial data prescribed on a Cauchy hypersurface Σ_0 crossing the future event horizon $\mathcal{H}^+$. We here obtain definitive energy and pointwise decay, non-decay and blow-up results. Our estimates hold up to and including the horizon $\mathcal{H}^+$. A hierarchy of conservations laws on degenerate horizons is also derived.

1. Introduction

In this paper we shall attempt to provide a complete picture of the stability and instability of extreme Reissner-Nordström backgrounds under linear scalar perturbations, extending the results of [1] on the wave equation

$$\Box_g\psi=0. \tag{1.1}$$

Here we derive definitive energy and pointwise decay, non-decay and blow-up results for solutions ψ to the wave equation and their derivatives in the domain of outer communications up to and including the event horizon $\mathcal{H}^+$. Note that the picture we obtain is in sharp contrast with the non-extreme case where decay holds for all higher order derivatives of ψ along $\mathcal{H}^+$.

1.1. Preliminaries.

The extreme Reissner-Nordström metric in coordinates $(v,r,\theta,\phi)\in\mathbb{R}\times\mathbb{R}^+\times\mathbb{S}^2$ takes the form

$$g=-Ddv^2+2dvdr+r^2g_{\mathbb{S}^2},$$

where M is a positive constant, $D=\left(1-\frac{M}{r}\right)^2$ and $g_{\mathbb{S}^2}$ is the standard metric on $\mathbb{S}^2$. The event horizon $\mathcal{H}^+$ corresponds to $r=M$, the black hole region to $r\leq M$ and the domain of outer communications to $r>M$. The photon sphere is located at $r=2M$.

For the reader's convenience we recall that the main results of [1] include: 1) non-degenerate energy and pointwise uniform boundedness of solutions, up to and including $\mathcal{H}^+$, 2) local integrated decay of energy, up to and including the event horizon $\mathcal{H}^+$, 3) sharp second order L^2 estimates, up to and including $\mathcal{H}^+$, 4) non-decay along $\mathcal{H}^+$ of higher order translation invariant quantities for spherically symmetric solutions.

Recall also that L^2 spacetime estimates which do not degenerate at the photon sphere require commutation with the Killing vector field $T=\partial_v$. This is the so-called trapping effect at the photon sphere. Note that another characteristic feature of degenerate horizons which was exposed in [1] is that obtaining L^2 spacetime estimates which do not degenerate at the horizon $\mathcal{H}^+$ requires commutation with the (non-Killing) vector field ∂_r and, therefore, loss of derivatives characteristic of trapping takes place on degenerate horizons in analogy to the photon sphere.

1.2. **Overview of Results and Techniques.**

In the present paper, we combine the previous results of [1] with certain new techniques to obtain definitive decay, non-decay and blow-up results. In particular, we present a method based on an adaptation of [16] to derive degenerate and non-degenerate energy decay. This adaptation requires the introduction of yet another vector field P and is necessary in view of the degeneracy of the surface gravity on the horizon. We also introduce a new method for obtaining sharp pointwise decay results. The instability properties of ψ (non-decay and blow-up for derivatives of ψ) rest upon a hierarchy of conservation laws on a specific class of degenerate horizons (which includes the extreme Reissner-Nordström) presented here for the first time. As we shall see, these laws are of great analytical importance.

1.2.1. *Conservation Laws on $\mathcal{H}^+$.* Recall that in [1] we derived a conservation law for the spherical mean ψ_0 of solutions ψ to the wave equation based on the degeneracy of the redshift along $\mathcal{H}^+$. However, as we shall see, on top of the degeneracy of the redshift, the event horizon satisfies an additional property which allows us to obtain a hierarchy of such laws. Specifically, we show that *a conservation law holds for every projection ψ_l of ψ (viewed as an L^2 function on the spheres of symmetry) on the eigenspace E^l of the spherical Laplacian $\Delta\!\!\!\!/$ (for all spherical harmonic numbers $l \in \mathbb{N}$).*

According to these laws a linear combination of the transversal derivatives of ψ_l of order at most $l+1$ is conserved along the null geodesics of $\mathcal{H}^+$ (see Theorem 1 of Section 2). As we shall see, these conserved quantities allow us to infer the instability properties of extreme black holes described in Section 1.2.4, and thus, understanding their structure is crucial and essential. Of course, no such conserved quantities exist in the subextreme case.

As an aside, based on these laws, we also explicitly show that the Schwarzschild boundedness argument of Kay and Wald [21] cannot be applied in the extreme case, i.e. we show that for generic ψ, there does not exist a Cauchy hypersurface Σ crossing $\mathcal{H}^+$ and a solution $\tilde{\psi}$ such that

$$T\tilde{\psi} = \psi$$

in the causal future of Σ (where $T = \partial_v$). The existence of such $\tilde{\psi}$ was key for the argument of [21].

1.2.2. *Sharp Higher Order L^2 Estimates.* We next establish higher order L^2 estimates of the derivatives of ψ by commuting repeatedly with the vector field ∂_r; see Theorem 2 of Section 2. In view of the conservation laws one expects to derive k'th order ($k \geq 1$) L^2 estimates close to $\mathcal{H}^+$ only if $\psi_l = 0$ for all $l \leq k$. In fact in Section 7 we show that if the above restriction on the frequency range is not satisfied then no such estimate can be derived. By using appropriate modifications and Hardy inequalities we obtain the sharpest possible result. See Section 4. Note that the spacetime term of such estimates degenerates with respect to the transversal derivative to $\mathcal{H}^+$. In order to retrieve this derivative one needs to commute once again with ∂_r, use Hardy inequalities and thus assume that an initial quantity of even higher order is bounded. This reflects *the higher order trapping effect present on $\mathcal{H}^+$* (recall that the case $k = 1$ was treated in [1]). The difficulty in deriving such L^2 estimates comes from the fact that the trapping effect is coupled with the low-frequency obstruction described in Section 1.2.1.

1.2.3. *Energy and Pointwise Decay.* Using an adaptation of the methods developed in the recent [16], we obtain energy and pointwise decay for ψ. See Theorems 3 and 4 of Section 2.

Recall that in [16], a general framework is provided for obtaining energy decay. The ingredients necessary for applying the framework are: 1) good asymptotics of the metric towards null infinity, 2) uniform boundedness of energy and 3) integrated local energy decay (where the spacetime integral of energy should be controlled by the energy of ψ and, in view of the trapping effect at the photon sphere, of $T\psi$ too). We first verify that extreme Reissner-Nordström satisfies the first hypothesis. However, in view of the trapping and the conservation laws on the event horizon $\mathcal{H}^+$, it turns out that the method described in [16] can not be directly used to yield decay results in the extreme case. Indeed, the third hypothesis of [16] is not satisfied in extreme Reissner-Nordström. For this reason, we introduce a new causal vector field P which allows us to obtain *several hierarchies of estimates in an appropriate neighbourhood of $\mathcal{H}^+$*. These estimates avoid multipliers or commutators with weights in t, following the philosophy of [16]. Our method applies to black hole spacetimes where trapping is present on $\mathcal{H}^+$ (including, in particular, a wide class of extreme black holes).

Pointwise decay for $l \geq 2$ then follows by commuting with the generators of so(3) and Sobolev estimates. Regarding the cases $l = 0, 1$, we present a new method which is based on the interpolation of previous estimates which hold close to $\mathcal{H}^+$ and away from $\mathcal{H}^+$. Note that the low angular frequencies decay more slowly than the higher ones. See Section 6.

We finally mention that Blue and Soffer have previously proved in [4] that a weighted L^6 norm in space decays like $t^{-\frac{1}{3}}$. However, this weight degenerates on the horizon and the initial data have to be supported away from $\mathcal{H}^+$.

1.2.4. *Higher Order Estimates: Energy and Pointwise Decay, Non-decay and Blow-up.* In order to provide a complete picture of the behaviour of solutions ψ, it remains to derive pointwise estimates for all derivatives of ψ. Let ψ_l denote the projection of ψ on the eigenspace E^l of the spherical Laplacian $\Delta\!\!\!\!/$, as above. Then the derivatives transversal to $\mathcal{H}^+$ of ψ_l decay if the order of the differentiation is at most l. If the order is $l+1$, then for generic initial data this derivative converges along $\mathcal{H}^+$ to a non-zero number and thus **does not decay**. By generic initial data we mean data for which certain quantities do not vanish on $\mathcal{H}^+$. If, moreover, the order is at least $l+2$, then for generic initial data these derivatives **blow up** asymptotically along $\mathcal{H}^+$. Note that these differential operators are translation invariant and do not depend on the choice of a coordinate system. *The blow-up of these geometric quantities suggests that extreme black holes are dynamically unstable.*

If, on the other hand, we consider the wave $T^m\psi_l$ then one needs to differentiate at least $l+2+m$ times in the transversal direction to obtain a quantity which blows up. See Theorems 5 and 6 of Section 2. Therefore, the T derivatives[1] counteract the action of the derivatives transversal to $\mathcal{H}^+$.

We conclude this paper by deriving similar decay and blow-up results for the higher order non-degenerate energy. In particular, we show that although (an appropriate modification of) the redshift current can be used as a multiplier for all angular frequencies, the redshift vector field N can only be used as a commutator for ψ supported on the frequencies $l \geq 1$ and, more generally, *one can commute with the redshift vector field at most l times for ψ supported on the angular frequency l.* See Section 7.

1.3. **Open Problems.** An important problem is that of understanding the solutions of the wave equation on the extreme Kerr spacetime. This spacetime is not spherically symmetric and there is no globally causal Killing field in the domain of outer communications (in particular, T becomes spacelike close to the event horizon). Recent results [18] overcome these difficulties for the whole subextreme range of Kerr. The extreme case remains open.

Another related problem is that of the wave equation coupled with the Einstein-Maxwell equations. Then decay for the scalar field was proven in the deep work of Dafermos and Rodnianski [12]. Again these results hold for non-extreme black holes. For the extreme case even boundedness of the scalar field for this system remains open.

2. The Main Theorems

We consider the Cauchy problem for the wave equation on the domain of outer communications of extreme Reissner-Nordström spacetimes (including $\mathcal{H}^+$) with initial data

$$\psi|_{\Sigma_0} = \psi_0 \in H^k_{\mathrm{loc}}(\Sigma_0), \, n_{\Sigma_0}\psi|_{\Sigma_0} = \psi_1 \in H^{k-1}_{\mathrm{loc}}(\Sigma_0), \tag{2.1}$$

where the hypersurface Σ_0 crosses $\mathcal{H}^+$ and terminates either at spacelike infinity i^0 or at null infinity $\mathcal{I}^+$ and n_{Σ_0} denotes the future unit normal of Σ_0. We assume that $k \geq 2$ and that

$$\lim_{x \to i^0} r\psi^2(x) = 0. \tag{2.2}$$

For simplicity, from now on, when we say "for all solutions ψ of the wave equation" we will assume that ψ satisfies the above conditions. Note that for obtaining sharp decay results we will have to consider even higher regularity for ψ.

---

[1] It is also shown that $T\psi$ decays faster than ψ.

2.1. **Notation.** For the definition of the relevant notions and notation used throughout the paper we refer to [1]. For the convenience of the reader, we briefly recall the notation (and conventions) necessary for understanding the statement of the main theorems. Let ψ_l denote the projection of ψ on the eigenspace E^l (with corresponding eigenvalue $-l(l+1), l \in \mathbb{N}$) of the spherical Laplacian $\Delta\!\!\!\!/$. We will say that ψ is supported on the angular frequencies $l \geq L$ if $\psi_i = 0, i = 0, ..., L-1$ initially (and thus everywhere). Similarly, we will also say that ψ is supported on the angular frequency $l = L$ if $\psi \in E^L$.

Let N be a $\varphi^T_\tau-$invariant timelike vector field which coincides with T away from $\mathcal{H}^+$ (as defined in Section 10 of [1]). The coordinate vector field ∂_r corresponds to the system (v, r) and is transversal to $\mathcal{H}^+$. Let T denote the globally causal and Killing vector field ∂_v. Let φ^T_τ denote the flow of T. We define the foliation $\Sigma_\tau = \varphi^T_\tau(\Sigma_0)$ and the region $\mathcal{R}(0,\tau) = \cup_{0 \leq \tilde{\tau} \leq \tau} \Sigma_{\tilde{\tau}}$.

Note that the energy currents $J^V_\mu[\psi], K^V[\psi]$ associated to the vector field V are defined in Section 5 of [1]. For reference, we mention that close to $\mathcal{H}^+$ we have

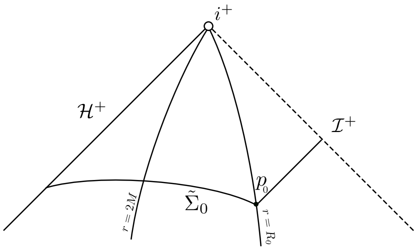
$$J^T_\mu[\psi] n^\mu_{\Sigma_\tau} \sim (T\psi)^2 + D(\partial_r \psi)^2 + \left|\nabla\!\!\!\!/ \psi\right|^2,$$

which degenerates on $\mathcal{H}^+$ (since $D = \left(1 - \frac{M}{r}\right)^2$), whereas

$$J^N_\mu[\psi] n^\mu_{\Sigma_\tau} \sim (T\psi)^2 + (\partial_r \psi)^2 + \left|\nabla\!\!\!\!/ \psi\right|^2,$$

which does not degenerate on $\mathcal{H}^+$.

For obtaining energy decay we shall make use of the $\tilde{\Sigma}_\tau$ foliation defined as follows: We fix $R_0 > 2M$ and consider the hypersurface $\tilde{\Sigma}_0$ which is spacelike for $M \leq r \leq R_0$ and crosses $\mathcal{H}^+$ and for $r \geq R_0$ is given by $u = u(p_0)$, where the coordinate u corresponds to the null system (u, v) with respect to which the metric is $g = -Ddudv + r^2 g_{\mathbb{S}^2}$, and the point $p_0 \in \tilde{\Sigma}_0$ is such that $r(p_0) = R_0$.



We now define $\tilde{\Sigma}_\tau = \varphi^T_\tau(\tilde{\Sigma}_0)$. Then for r sufficiently large we have

$$J^T_\mu[\psi] n^\mu_{\tilde{\Sigma}_\tau} \sim (\partial_v \psi)^2 + \left|\nabla\!\!\!\!/ \psi\right|^2,$$

where ∂_v corresponds here to the null coordinate system (u, v).

2.2. **Summary of Results of Part I.** It would be helpful to summarize several of the results of [1] at this point. We have

(1) Uniform boundedness of non-degenerate energy:

$$\int_{\Sigma_\tau} J^N_\mu[\psi] n^\mu_{\Sigma_\tau} \leq C \int_{\Sigma_0} J^N_\mu[\psi] n^\mu_{\Sigma_0}.$$

(2) Local integrated decay of energy:

$$\int_{\mathcal{R}(0,\tau)} \left(\frac{(r-2M)^2 \cdot \sqrt{D}}{r^{3+\delta}} \left((T\psi)^2 + \left|\nabla\!\!\!\!/ \psi\right|^2 + D^2 (\partial_r \psi)^2 + \frac{1}{r^2}\psi^2 \right) \right) \leq C_\delta \int_{\Sigma_0} J^T_\mu[\psi] n^\mu_{\Sigma_0}.$$

Note that the above estimate degenerates on the photon sphere (where $r = 2M$) and the event horizon. In order to remove the degeneracy on the photon sphere we need to commute with the vector field T. This is related to the so-called trapping effect present on the photon sphere. Note that the same phenomenon takes place on the 'photon spheres' of a wide class of black hole spacetimes. Furthermore, as is shown in [1], the degeneracy of the above estimate on $\mathcal{H}^+$ may only be removed after commuting with the (non-Killing) vector field ∂_r. This revealed that degenerate horizons exhibit phenomena characteristic of trapping. This will be of fundamental importance for the analysis of the present paper.

(3) Sharp Second Order L^2 Estimates: There exists r_0 such that $M < r_0 < 2M$ and if $\mathcal{A} = \mathcal{R}(0,\tau) \cap \{M \leq r \leq r_0\}$ then for all ψ supported on the angular frequencies $l \geq 1$, the following holds:

$$\begin{aligned}&\int_{\Sigma_\tau\cap\mathcal{A}} (T\partial_r\psi)^2 + (\partial_r\partial_r\psi)^2 + |\nabla\!\!\!/\,\partial_r\psi|^2 + \int_{\mathcal{H}^+} (T\partial_r\psi)^2 + \chi_1 |\nabla\!\!\!/\,\partial_r\psi|^2 \\ &+ \int_{\mathcal{A}} (T\partial_r\psi)^2 + \sqrt{D}\,(\partial_r\partial_r\psi)^2 + |\nabla\!\!\!/\,\partial_r\psi|^2 \\ &\leq C\int_{\Sigma_0} J^N_\mu[\psi]n^\mu_{\Sigma_0} + C\int_{\Sigma_0} J^N_\mu[T\psi]n^\mu_{\Sigma_0} + C\int_{\Sigma_0\cap\mathcal{A}} J^N_\mu[\partial_r\psi]n^\mu_{\Sigma_0},\end{aligned}$$

where $\chi_1 = 0$ if ψ is supported on $l = 1$ and $\chi_1 = 1$ if ψ is supported on $l \geq 2$.

(4) Non-decay (for generic initial data) of the higher order quantity

$$\psi^2 + (\partial_r\psi)^2$$

along $\mathcal{H}^+$.

2.3. **The Statements of the Main Theorems.** The main results of the present paper are:

Theorem 1. ***(Conservation Laws along $\mathcal{H}^+$)*** *For all $l \in \mathbb{N}$ there exist constants $\beta_i, i = 0, 1, ..., l$, which depend on M and l such that for all solutions ψ which are supported on the (fixed) angular frequency l the quantity*

$$H_l[\psi] = \partial_r^{l+1}\psi + \sum_{i=0}^{l} \beta_i \partial_r^i \psi$$

is conserved along the null geodesics of $\mathcal{H}^+$.

Theorem 2. ***(Higher Order L^2 Estimates: Trapping on $\mathcal{H}^+$)***

(1) *There exists r_0 such that $M < r_0 < 2M$ and a constant $C > 0$ which depends on M, l and Σ_0 such that if $\mathcal{A} = \{M \leq r \leq r_0\} \cap \mathcal{R}(0,\tau)$ and $k \leq l$ then for all solutions ψ of the wave equation which are supported on frequencies greater or equal to l, the following holds*

$$\begin{aligned}&\int_{\Sigma_\tau\cap\mathcal{A}} \left(T\partial_r^k\psi\right)^2 + \left(\partial_r^{k+1}\psi\right)^2 + \left|\nabla\!\!\!/\,\partial_r^k\psi\right|^2 + \int_{\mathcal{H}^+} \left(T\partial_r^k\psi\right)^2 + \chi_{\{k=l\}} \left|\nabla\!\!\!/\,\partial_r^k\psi\right|^2 \\ &+ \int_{\mathcal{A}} \left(T\partial_r^k\psi\right)^2 + \left(1 - \frac{M}{r}\right)\left(\partial_r^{k+1}\psi\right)^2 + \left|\nabla\!\!\!/\,\partial_r^k\psi\right|^2 \\ &\leq C\sum_{i=0}^{k} \int_{\Sigma_0} J^N_\mu\left[T^i\psi\right] n^\mu_{\Sigma_0} + C\sum_{i=1}^{k} \int_{\Sigma_0\cap\mathcal{A}} J^N_\mu\left[\partial_r^i\psi\right] n^\mu_{\Sigma_0},\end{aligned}$$

where $\chi_{\{k=l\}} = 0$ if $k = l$ and $\chi_{\{k=l\}} = 1$ otherwise.

(2) *If ψ is replaced with $T^m\psi, m \geq 1$, then similar L^2 estimates hold for all $k \leq l + m$. Also in this case, for all $k \leq l + m$ we do not need the factor $\chi_{\{k=l\}}$.*

Remark 2.1. *In view of the $\left(1 - \frac{M}{r}\right)$ factor, the spacetime term of the above estimate degenerates on $\mathcal{H}^+$. To remove this degeneracy one needs to lose even more derivatives by commuting with the vector field ∂_r one more time. This reflects the higher order trapping effect of $\mathcal{H}^+$. The commutation with T is related to the trapping on the photon sphere.*

Theorem 3. *(**Energy Decay**) Consider the foliation $\tilde{\Sigma}_\tau$ as defined above. Let*

$$I^T_{\tilde{\Sigma}_\tau}[\psi]=\int_{\tilde{\Sigma}_\tau}J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}+\int_{\tilde{\Sigma}_\tau}J^T_\mu[T\psi]n^\mu_{\tilde{\Sigma}_\tau}+\int_{\tilde{\Sigma}_\tau}r^{-1}\left(\partial_v(r\psi)\right)^2$$

and

$$I^N_{\tilde{\Sigma}_\tau}[\psi]=\int_{\tilde{\Sigma}_\tau}J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}+\int_{\tilde{\Sigma}_\tau}J^N_\mu[T\psi]n^\mu_{\tilde{\Sigma}_\tau}+\int_{\mathcal{A}\cap\tilde{\Sigma}_\tau}J^N_\mu[\partial_r\psi]n^\mu_{\tilde{\Sigma}_\tau}+\int_{\tilde{\Sigma}_\tau}r^{-1}\left(\partial_v(r\psi)\right)^2,$$

where $\mathcal{A}$ is as defined in Theorem 2. Here ∂_v corresponds to the null system (u,v) (whereas ∂_r still corresponds to the Eddington-Finkelstein coordinate system (v,r)). There exists a constant C that depends on the mass M and $\tilde{\Sigma}_0$ such that:

- *For all solutions ψ of the wave equation we have*

$$\int_{\tilde{\Sigma}_\tau}J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq CE_1[\psi]\frac{1}{\tau^2},$$

  where

$$E_1[\psi]=I^T_{\tilde{\Sigma}_0}[T\psi]+\int_{\tilde{\Sigma}_0}J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_0}+\int_{\tilde{\Sigma}_0}\left(\partial_v(r\psi)\right)^2.$$

- *For all solutions ψ to the wave equation which are supported on the frequencies $l\geq 1$ we have*

$$\int_{\tilde{\Sigma}_\tau}J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq CE_2[\psi]\frac{1}{\tau},$$

  where

$$E_2[\psi]=I^N_{\tilde{\Sigma}_0}[\psi].$$

- *For all solutions ψ to the wave equation which are supported on the frequencies $l\geq 2$ we have*

$$\int_{\tilde{\Sigma}_\tau}J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq CE_3[\psi]\frac{1}{\tau^2},$$

  where

$$E_3[\psi]=I^N_{\tilde{\Sigma}_0}[\psi]+I^N_{\tilde{\Sigma}_0}[T\psi]+\int_{\mathcal{A}\cap\tilde{\Sigma}_0}J^N_\mu[\partial_r\partial_r\psi]n^\mu_{\tilde{\Sigma}_0}+\int_{\tilde{\Sigma}_0}\left(\partial_v(r\psi)\right)^2.$$

Remark 2.2. *In view of the trapping effect on $\mathcal{H}^+$, to obtain decay of the non-degenerate energy we need to 'lose' the ∂_r derivative (which appears in $I^N_{\tilde{\Sigma}_0}[\psi]$). Note that the full decay requires 'losing' the higher order derivative $\partial_r\partial_r$ (which appears in $E_3[\psi]$).*

Theorem 4. *(**Pointwise Decay**) Fix R_1 such that $M<R_1$ and let $\tau\geq 1$. Let E_1,E_2,E_3 be the quantities as defined in Theorem 3. Then, there exists a constant C that depends on the mass M, R_1 and $\tilde{\Sigma}_0$ such that:*

- *For all solutions ψ to the wave equation we have*

$$|\psi|\leq C\sqrt{E_5}\frac{1}{\sqrt{r}\cdot\tau},\quad |\psi|\leq C\sqrt{E_5}\frac{1}{r\cdot\sqrt{\tau}}$$

  in $\{R_1\leq r\}$, where

$$E_5=\sum_{|k|\leq 2}E_1\left[\Omega^k\psi\right],$$

  with $\Omega\in\{\Omega_1,\Omega_2,\Omega_3\}$ and $\Omega_i, i=1,2,3$ are the angular momentum operators.

- *For all solutions ψ of the wave equation we have*

$$|\psi|\leq C\sqrt{E_6}\frac{1}{\tau^{\frac{3}{5}}}$$

  in $\{M\leq r\leq R_1\}$, where

$$E_6=E_1+E_4[\psi]+E_4[T\psi]+E_5+\sum_{|k|\leq 2}\left(E_2\left[\Omega^k\psi\right]+E_3\left[\Omega^k\psi\right]\right)+\|\partial_r\psi\|^2_{L^\infty(\tilde{\Sigma}_0)}.$$

- *For all solutions ψ to the wave equation which are supported on the frequencies $l \geq 1$ we have*
$$|\psi| \leq C\sqrt{E_7}\frac{1}{\tau^{\frac{3}{4}}}$$
in $\{M \leq r \leq R_1\}$, where
$$E_7 = E_5 + \sum_{|k|\leq 2} E_2\left[\Omega^k\psi\right] + \sum_{|k|\leq 2} E_3\left[\Omega^k\psi\right].$$
- *For all solutions ψ to the wave equation which are supported on the frequencies $l \geq 2$ we have*
$$|\psi| \leq C\sqrt{E_8}\frac{1}{\tau},$$
in $\{M \leq r \leq R_1\}$, where
$$E_8 = \sum_{|k|\leq 2} E_3\left[\Omega^k\psi\right].$$

Theorem 5. ***(Higher Order Energy and Pointwise Estimates I: Decay Results)*** *Fix R_1 such that $R_1 > M$ and let $\tau \geq 1$. Let also $k, l, m \in \mathbb{N}$. Then, there exist constants C which depend on M, l, k, R_1 and $\tilde{\Sigma}_0$ such that the following holds: For all solutions ψ of the wave equation which are supported on the (fixed) angular frequency l, there exist norms $\tilde{E}_{k,l,m}$, $E_{k,l,m}$ of the initial data of ψ such that*

(1) $\displaystyle\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}} J^N_\mu[\partial_r^k T^m\psi]n^\mu_{\tilde{\Sigma}_\tau} \leq C\tilde{E}^2_{k,l,m}\frac{1}{\tau^2}$ *for all $k \leq l+m-2$,*

(2) $\displaystyle\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}} J^N_\mu[\partial_r^{l+m-1} T^m\psi]n^\mu_{\tilde{\Sigma}_\tau} \leq C\tilde{E}^2_{l+m-1,l,m}\frac{1}{\tau}.$

(3) $\left|\partial_r^k T^m\psi\right| \leq CE_{k,l,m}\frac{1}{\tau}$ *in $\{M \leq r \leq R_1\}$ for all $k \leq l-2+m$,*

(4) $\left|\partial_r^{l+m-1} T^m\psi\right| \leq CE_{l+m-1,l,m}\frac{1}{\tau^{\frac{3}{4}}}$ *in $\{M \leq r \leq R_1\}$,*

(5) $\left|\partial_r^{l+m} T^m\psi\right| \leq CE_{l+m,l,m}\frac{1}{\tau^{\frac{1}{4}}}$ *in $\{M \leq r \leq R_1\}$,*

Theorem 6. ***(Higher Order Energy and Pointwise Estimates II: Non-Decay and Blow-up Results)*** *Fix R_1 such that $R_1 > M$. Let $k, l, m \in \mathbb{N}$ and $H_l[\psi]$ be the functions as defined in Theorem 1. Then there exist non zero constants C, c (in fact $c > 0$) which depend on M, l, k, R_1 such that for generic solutions ψ to the wave equation which are supported on the (fixed) angular frequency l we have*

(1)
$$\partial_r^{l+m+1}T^m\psi(\tau,\theta,\phi) \to CH_l[\psi](\theta,\phi)$$
as $\tau \to +\infty$ along $\mathcal{H}^+$ and generically $H_l[\psi] \neq 0$ almost everywhere on $\mathbb{S}^2_0 = \tilde{\Sigma}_0 \cap \mathcal{H}^+$ (and $C = 1$ for $m = 0$).

(2)
$$\left|\partial_r^{l+m+k}T^m\psi\right|(\tau,\theta,\phi) \geq c\left|H_l[\psi](\theta,\phi)\right|\tau^{k-1}$$
asymptotically on $\mathcal{H}^+$ for all $k \geq 2$.

Finally, for generic solutions ψ to the wave equation we have
$$\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}} J^N_\mu[\partial_r^k T^m\psi]n^\mu_{\tilde{\Sigma}_\tau} \longrightarrow +\infty$$
as $\tau \to +\infty$ for all $k \geq m+1$.

3. CONSERVATION LAWS ON DEGENERATE EVENT HORIZONS

We will prove that the lack of redshift gives rise to conservation laws along $\mathcal{H}^+$ for translation invariant derivatives. These laws govern the evolution of the low angular frequencies and play a fundamental role in understanding the evolution of generic solutions to the wave equation.

We use the regular coordinate system (v,r). Let $T=\partial_v$, where ∂_v denotes the coordinate vector field corresponding to the system (v,r). As we shall see our results can be applied to a general class of (spherically symmetric) degenerate black hole spacetimes. We conclude this section by showing that the argument of Kay and Wald (see [21]) could not have been applied in our case even for obtaining uniform boundedness of the solutions to the wave equation.

Let us first consider spherically symmetric solutions.

Proposition 3.0.1. *For all spherically symmetric solutions ψ to the wave equation the quantity*

$$H_0[\psi]=\partial_r\psi+\frac{1}{M}\psi \tag{3.1}$$

is conserved along $\mathcal{H}^+$.

Proof. Since ψ solves $\Box_g\psi=0$ and since $\slashed{\Delta}\psi=0$ we have $T\partial_r\psi+\frac{1}{M}T\psi=0$ and, since T is tangential to $\mathcal{H}^+$, this implies that $\partial_r\psi+\frac{1}{M}\psi$ remains constant along $\mathcal{H}^+$. $\square$

Proposition 3.0.2. *For all solutions ψ to the wave equation that are supported on the angular frequency $l=1$ the quantity*

$$H_1[\psi]=\partial_r\partial_r\psi+\frac{3}{M}\partial_r\psi+\frac{1}{M^2}\psi \tag{3.2}$$

is conserved along the null geodesics of $\mathcal{H}^+$.

Proof. Since $\slashed{\Delta}\psi=-\frac{2}{r^2}\psi$, the wave equation on $\mathcal{H}^+$ gives us

$$2T\partial_r\psi+\frac{2}{M}T\psi=\frac{2}{M^2}\psi. \tag{3.3}$$

Moreover if $R=D'+\frac{2D}{r}$ then

$$\partial_r\left(\Box_g\psi\right)=D\partial_r\partial_r\partial_r\psi+2T\partial_r\partial_r\psi+\frac{2}{r}\partial_rT\psi+R\partial_r\partial_r\psi+\partial_r\slashed{\Delta}\psi+D'\partial_r\partial_r\psi-\frac{2}{r^2}T\psi+R'\partial_r\psi$$

and thus by restricting this identity on $\mathcal{H}^+$ we take

$$2\partial_r^2T\psi+\frac{2}{M}\partial_rT\psi-\frac{2}{M^2}T\psi+\frac{4}{M^3}\psi+\left(-\frac{2}{M^2}+R'(M)\right)\partial_r\psi=0. \tag{3.4}$$

However, $R'(M)=\frac{2}{M^2}$ and in view of (3.3) we have

$$2\partial_r^2T\psi+\frac{2}{M}\partial_rT\psi-\frac{2}{M^2}T\psi+\frac{2}{M}\left(2\partial_rT\psi+\frac{2}{M}T\psi\right)=0$$

which means that (3.2) is constant along the integral curves of T on $\mathcal{H}^+$. $\square$

Proposition 3.0.3. *There exist constants α_i^j, $j=0,1,...,l-1$, $i=0,1,...,j+1$, which depend on M and l such that for all solutions ψ of the wave equation which are supported on the (fixed) frequency l we have*

$$\partial_r^j\psi=\sum_{i=0}^{j+1}\alpha_i^jT\partial_r^i\psi,$$

on $\mathcal{H}^+$.

Proof. For $j=0,1$ we just have to revisit the proof of Proposition 3.0.2 and use the fact that for all $l\geq 2$ we have $-\frac{l(l+1)}{M^2}+R'(M)\neq 0$. We next proceed by induction on j for fixed l. We suppose that the result holds for $j = 0, 1, ..., k-1$ and we will prove that it holds for $j = k$ provided $k \leq l-1$. Clearly,

$$\begin{aligned} \partial_r^k\left(\Box_g\psi\right) =& D\left(\partial_r^{k+2}\psi\right) + 2\partial_r^{k+1}T\psi + \frac{2}{r}\partial_r^k T\psi + R\partial_r^{k+1}\psi + \partial_r^k \slashed{\Delta}\psi + \\ &+ \sum_{i=1}^{k}\binom{k}{i}\partial_r^i D\cdot\partial_r^{k-i+2}\psi + \sum_{i=1}^{k}\binom{k}{i}\partial_r^i\frac{2}{r}\cdot\partial_r^{k-i}T\psi + \sum_{i=1}^{k}\binom{k}{i}\partial_r^i R\cdot\partial_r^{k-i+1}\psi. \end{aligned} \tag{3.5}$$

We observe that the coefficients of $\partial_r^{k+2}\psi$ and $\partial_r^{k+1}\psi$ vanish on $\mathcal{H}^+$. Since $\slashed{\Delta}\psi = -\frac{l(l+1)}{r^2}\psi$, the coefficient of $\partial_r^k\psi$ on $\mathcal{H}^+$ is equal to

$$\binom{k}{2}D'' + \binom{k}{1}R' - \frac{l(l+1)}{M^2} = \frac{k(k+1)}{2}\frac{2}{M^2} - \frac{l(l+1)}{M^2}, \tag{3.6}$$

which is non-zero if and only if $l \neq k$. Therefore, for all $k \leq l-1$ we can solve with respect to $\partial_r^k\psi$ and use the inductive hypothesis completing thus the proof of the proposition. □

Proof of Theorem 1 of Section 2. We apply (3.5) for $k = l$. Then, according to our previous calculation, the coefficients of $\partial_r^{l+2}\psi$, $\partial_r^{l+1}\psi$ and $\partial_r^l\psi$ vanish on $\mathcal{H}^+$. Therefore, we end up with the terms $\partial_r^k T\psi, k = 0, 1, ..., l+1$ and $\partial_r^j\psi, j = 0, 1, ..., l-1$. Thus, from Proposition 3.0.3 there exist constants $\beta_i, i = 0, 1, ..., l$ which depend on M and l such that

$$T\partial_r^{l+1}\psi + \sum_{i=0}^{l}\beta_i T\partial_r^i\psi = 0$$

on $\mathcal{H}^+$, which implies that the quantity

$$H_l[\psi] = \partial_r^{l+1}\psi + \sum_{i=0}^{l}\beta_i\partial_r^i\psi$$

is conserved along the integral curves of T on $\mathcal{H}^+$. □

Note that the above theorem holds for more general extreme black hole spacetimes. Indeed, let the metric with respect to the coordinate system (v, r, θ, ϕ) take the form

$$g = -Ddv^2 + 2dvdr + r^2 g_{\mathbb{S}^2},$$

for a general $D = D(r)$. If this spacetime admits a black hole whose event horizon is located at $r = r_{\mathcal{H}^+}$ where $D(r_{\mathcal{H}^+}) = 0$, then the above theorem (and proof) still holds if

$$D'(r_{\mathcal{H}^+}) = 0, \tag{3.7}$$

$$D''(r_{\mathcal{H}^+}) = \frac{2}{r_{\mathcal{H}^+}^2}. \tag{3.8}$$

The equation (3.7) expresses the extremality of the black hole whereas the additional (3.8) is necessary so (3.6) holds. Note here that (3.6) trivially holds for the frequency $l = 0$ and thus (3.8) is not required for spherically symmetric solutions of the wave equation. In [2], we provide even more general assumptions under which we have conservation laws for spherically symmetric self-gravitating scalar fields on extreme black holes.

3.1. **Applications.** Note that although we show in Section 7 that $H_l[\psi]$ is non-zero almost everywhere on $\mathcal{H}^+ \cap \Sigma_0$ for generic initial data, we have $H_l[T^m\psi] = 0$ for all ψ and $m \geq 1$. For the waves of the form $T^m\psi$ we have the following

Proposition 3.1.1. *There exist constants $C \neq 0$ and λ_{ij} which depend on M, l, m and such that for all solutions of the wave equation which are supported on the frequency l we have*

$$\partial_r^{l+m+1}T^m\psi + \sum_{j=0}^{m}\sum_{i=0}^{l}\lambda_{ij}\partial_r^i T^j\psi = C\cdot H_l[\psi]$$

on $\mathcal{H}^+$.

Proof. Consider (3.5) for $k=l+1$. Then

$$\begin{aligned}0=2\partial_r^{l+2}T\psi+\frac{2}{M}\partial_r^{l+1}T\psi+\partial_r^{l+1}\left(-\frac{l(l+1)}{r^2}\psi\right)+\\+\sum_{i=2}^{l+1}\binom{l+1}{i}\partial_r^iD\cdot\partial_r^{l-i+3}\psi+\sum_{i=1}^{l+1}\binom{l+1}{i}\partial_r^i\frac{2}{r}\cdot\partial_r^{l+1-i}T\psi+\sum_{i=1}^{l+1}\binom{l+1}{i}\partial_r^iR\cdot\partial_r^{l-i+2}\psi.\end{aligned}$$

Since $H_l[T\psi]=0$, the term $\partial_r^{l+1}T\psi$ can be expressed in terms of $T\psi,\partial_rT\psi,...,\partial_r^lT\psi$. Note also $\partial_r^{l+1}\psi$, whose coefficient on the right hand side is non-zero, can be replaced by a linear expression of $H_l[\psi],\psi,\partial_r\psi,...,\partial_r^l\psi$. This proves the proposition for $m=1$. The general case can be proved inductively by using (3.5) for $k=l+m$ and ψ replaced with $T^{m-1}\psi$. Indeed, we obtain that $\partial_r^{l+m+1}T^m\psi$ can be expressed on $\mathcal{H}^+$ as a linear combination of the terms $\partial_r^{l+m}T^m\psi,\partial_r^{l+m}T^{m-1}\psi$ and $\partial_r^kT^m\psi$ and $\partial_r^kT^{m-1}\psi$ for $k\leq l+m-1$. For the terms $\partial_r^{l+m}T^m\psi,\partial_r^kT^m\psi,\partial_r^kT^{m-1}\psi$ with $k\leq l+m-1$ we use the inductive hypothesis and that $H_l[T^i\psi]=0$ for all $i\geq 1$. Note finally that the coefficient of $\partial_r^{l+m}T^{m-1}\psi$ is non-zero and, therefore, this term can be replaced by a linear combination of $H_l[\psi]$ and $\partial_r^iT^j\psi$ for $i\leq l,j\leq m$. □

We conclude this section with the following important application of Theorem 1.

Proposition 3.1.2. *For generic initial data there is no Cauchy hypersurface Σ crossing $\mathcal{H}^+$ and a solution $\tilde{\psi}$ of the wave equation such that*

$$T\tilde{\psi}=\psi$$

in the future of Σ.

Proof. Suppose that there exists a wave $\tilde{\psi}$ such that $T\tilde{\psi}=\psi$. Then we can decompose $\tilde{\psi}=\tilde{\psi}_0+\tilde{\psi}_{\geq 1}$ and take

$$T\tilde{\psi}=T\tilde{\psi}_0+T\tilde{\psi}_{\geq 1}=(T\tilde{\psi})_0+(T\tilde{\psi})_{\geq 1}$$

since T is an endomorphism of the eigenspaces of $\slashed{\Delta}$. But $T\tilde{\psi}=\psi$ and thus $\psi_0=(T\tilde{\psi})_0=T\tilde{\psi}_0$. Since $\tilde{\psi}_0$ is a spherically symmetric wave we have $\partial_rT\tilde{\psi}_0+\frac{1}{M}T\tilde{\psi}_0=0$ which yields $\partial_r\psi_0+\frac{1}{M}\psi_0=0$. However,the quantity $\partial_r\psi_0+\frac{1}{M}\psi_0$ is completely determined by the initial data and thus for generic initial data it is non-zero. □

This shows that we can not adapt the argument of Kay and Wald for the extreme case (see [20] and [21]) even for proving the uniform boundedness of solutions to the wave equation. Indeed, using this argument one could prove that in Schwarzschild that for any solution of the wave equation ψ there is another solution $\tilde{\psi}$ such that $T\tilde{\psi}=\psi$ in the future of a Cauchy hypersurface Σ of the region $J^+(\Sigma)\cap\mathcal{D}$, where $\mathcal{D}$ denotes the domain of outer communications of Schwarzschild.

4. Sharp Higher Order L^2 Estimates

We commute the wave equation with ∂_r^k where $k\in\mathbb{N}$ and $k\geq 2$ aiming at controlling all higher derivatives of ψ (on the spacelike hypersurfaces and the spacetime region up to and including the horizon $\mathcal{H}^+$). In view of Theorem 1 of Section 2 the weakest condition on ψ would be such that it is supported on the frequencies $l\geq k$.

4.1. The Commutator $\left[\Box_g,\partial_r^k\right]$.

First note that if $R=D'+\frac{D}{2r},D'=\frac{dD}{dr}$ then

$$\begin{aligned}\partial_r^k\left(\Box_g\psi\right)=&D\left(\partial_r^{k+2}\psi\right)+2T\partial_r^{k+1}\psi+\frac{2}{r}T\partial_r^k\psi+R\partial_r^{k+1}\psi+\partial_r^k\slashed{\Delta}\psi+\\&+\sum_{i=1}^{k}\binom{k}{i}\partial_r^iD\cdot\partial_r^{k-i+2}\psi+\sum_{i=1}^{k}\binom{k}{i}\partial_r^i\frac{2}{r}\cdot T\partial_r^{k-i}\psi+\sum_{i=1}^{k}\binom{k}{i}\partial_r^iR\cdot\partial_r^{k-i+1}\psi.\end{aligned}$$

Let us compute the commutator $\left[\not\Delta, \partial_r^k\right]$. If we denote $\not\Delta_1$ the Laplacian on the unit sphere then

$$\begin{aligned}\partial_r^k \not\Delta\psi = \partial_r^k\left(\frac{1}{r^2}\not\Delta_1\right) &= \sum_{i=0}^{k}\binom{k}{i}\partial_r^i\frac{1}{r^2}\cdot\partial_r^{k-i}\not\Delta_1 = \sum_{i=0}^{k}\binom{k}{i}r^2\partial_r^i\frac{1}{r^2}\cdot\not\Delta\partial_r^{k-i}\psi\\ &= \not\Delta\partial_r^k\psi + \sum_{i=1}^{k}\binom{k}{i}r^2\partial_r^i r^{-2}\cdot\not\Delta\partial_r^{k-i}\psi.\end{aligned}$$

Therefore,

$$\left[\not\Delta, \partial_r^k\right]\psi = -\sum_{i=1}^{k}\binom{k}{i}r^2\partial_r^i r^{-2}\cdot\not\Delta\partial_r^{k-i}\psi \tag{4.1}$$

and so

$$\begin{aligned}\left[\Box_g, \partial_r^k\right]\psi = &-\sum_{i=1}^{k}\binom{k}{i}\partial_r^i D\cdot\partial_r^{k-i+2}\psi - \sum_{i=1}^{k}\binom{k}{i}\partial_r^i\frac{2}{r}\cdot T\partial_r^{k-i}\psi\\ &-\sum_{i=1}^{k}\binom{k}{i}\partial_r^i R\cdot\partial_r^{k-i+1}\psi - \sum_{i=1}^{k}\binom{k}{i}r^2\partial_r^i r^{-2}\cdot\not\Delta\partial_r^{k-i}\psi.\end{aligned} \tag{4.2}$$

4.2. **Induction on l.** For any solution ψ of the wave equation we control the higher order derivatives in the spacetime region away from $\mathcal{H}^+$ and the photon sphere:

$$\left\|\partial_\alpha\psi\right\|^2_{L^2(\mathcal{R}(0,\tau)\cap\{M<r_0\leq r\leq r_1<2M\})} \leq C\int_{\Sigma_0}\left(\sum_{i=0}^{k-1}J_\mu^T\left[T^i\psi\right]n^\mu_{\Sigma_0}\right), \tag{4.3}$$

where C depends on M, r_0, r_1 and Σ_0 and $|a| = k$. This can be proved by commuting the wave equation with $T^i, i = 1, ..., k-1$ and using the degenerate X estimate of Theorem 1 of [1] and local elliptic estimates. We next derive estimates controlling the k^{th}-order derivatives of ψ in a neighbourhood of $\mathcal{H}^+$.

Proof of Theorem 2 of Section 2. For simplicity we write $\mathcal{R}$ instead of $\mathcal{R}(0,\tau)$ and $\mathcal{H}^+$ instead of $\mathcal{H}^+\cap\mathcal{R}(0,\tau)$. We follow an inductive process. We suppose that the theorem holds for all m such that $0 \leq m \leq l-1$, i.e. that there exists a neighbourhood $\mathcal{A}$ of $\mathcal{H}^+$ and a uniform positive constant C that depends on M, Σ_0 and k such that

$$\begin{aligned}&\int_{\Sigma_\tau\cap\mathcal{A}}\left(T\partial_r^k\psi\right)^2 + \left(\partial_r^{k+1}\psi\right)^2 + \left|\not\nabla\partial_r^k\psi\right|^2 + \int_{\mathcal{H}^+}\left(T\partial_r^k\psi\right)^2 + \chi_{\{k=m\}}\left|\not\nabla\partial_r^k\psi\right|^2\\ &+\int_{\mathcal{A}}\left(T\partial_r^k\psi\right)^2 + \sqrt{D}\left(\partial_r^{k+1}\psi\right)^2 + \left|\not\nabla\partial_r^k\psi\right|^2\\ \leq &C\sum_{i=0}^{k}\int_{\Sigma_0}J_\mu^N\left[T^i\psi\right]n^\mu_{\Sigma_0} + C\sum_{i=1}^{k}\int_{\Sigma_0\cap\mathcal{A}}J_\mu^N\left[\partial_r^i\psi\right]n^\mu_{\Sigma_0}\end{aligned} \tag{4.4}$$

for all $k \leq m$ and solutions supported on frequencies greater or equal to m. Note that for $m = 0$ the above estimate is the result of Section 11 and for $m = 1$ of Section 12 of [1].

In order to show the above estimate for $m = l$ we will construct an appropriate multiplier $L_k = L_k^v T + L_k^r\partial_r$ which is a future directed causal φ_τ^T-invariant vector field such that $L_k = \mathbf{0}$ in $r \geq r_1$ and timelike in the region $M < r_1$. The precise form of L_k^v, L_k^r will be chosen only in the end. Again, we will be interested in the region $\{M \leq r \leq r_0 < r_1\}$, where r_0, r_1 are to be determined later. The control for the higher order derivatives will be derived from the energy identity of the current $J_\mu^{L_k}\left[\partial_r^k\psi\right]$

$$\int_{\Sigma_\tau}J_\mu^{L_k}[\partial_r^k\psi]\,n^\mu_{\Sigma_\tau} + \int_{\mathcal{R}}\nabla^\mu J_\mu^{L_k}[\partial_r^k\psi] + \int_{\mathcal{H}^+}J_\mu^{L_k}[\partial_r^k\psi]\,n^\mu_{\mathcal{H}^+} = \int_{\Sigma_0}J_\mu^{L_k}[\partial_r^k\psi]\,n^\mu_{\Sigma_0}. \tag{4.5}$$

By assumption, the right hand side is bounded. Also, since L_k is timelike in a spatially compact region, we have

$$J_\mu^{L_k}[\partial_r^k\psi]\, n^\mu_{\Sigma_\tau} \sim \left(T\partial_r^k\psi\right)^2 + \left(\partial_r^{k+1}\psi\right)^2 + \left|\nabla\!\!\!\!/\,\partial_r^k\psi\right|^2 \tag{4.6}$$

and on the horizon

$$J_\mu^{L_k}[\partial_r^k\psi]\, n^\mu_{\mathcal{H}^+} = L_k^v(M)\left(T\partial_r^k\psi\right)^2 - \frac{L_k^r(M)}{2}\left|\nabla\!\!\!\!/\,\partial_r^k\psi\right|^2. \tag{4.7}$$

Note that $L_k^r<0$ on the horizon. It suffices to estimate the bulk integral. We have

$$\nabla^\mu J_\mu^{L_k}[\partial_r^k\psi] = K^{L_k}\left[\partial_r^k\psi\right] + \mathcal{E}^{L_k}\left[\partial_r^k\psi\right].$$

Recall that

$$K^{L_k}\left[\partial_r^k\psi\right] = F_{vv}(T\partial^k\psi)^2 + F_{rr}(\partial^{k+1}\psi)^2 + F_{\nabla\!\!\!\!/}\left|\nabla\!\!\!\!/\,\partial^k\psi\right|^2 + F_{vr}(T\partial^k\psi)(\partial^{k+1}\psi),$$

where the coefficients F_{ab} are given by

$$F_{vv} = \left(\partial_r L_k^v\right), F_{rr} = D\left[\frac{(\partial_r L_k^r)}{2} - \frac{L_k^r}{r}\right] - \frac{L_k^r D'}{2}, F_{\nabla\!\!\!\!/} = -\frac{1}{2}\left(\partial_r L_k^r\right), F_{vr} = D\left(\partial_r L_k^v\right) - \frac{2L_k^r}{r}.$$

Equation (4.2) gives us

$$\begin{aligned}
&\mathcal{E}^{L_k}\left[\partial_r^k\psi\right] = \left(\Box_g\partial_r^k\psi\right) L_k\left[\partial_r^k\psi\right]\\
=&\left[-\sum_{i=1}^{k}\binom{k}{i}\partial_r^i D\cdot\partial_r^{k-i+2}\psi - \sum_{i=1}^{k}\binom{k}{i}\partial_r^i\frac{2}{r}\cdot T\partial_r^{k-i}\psi\right.\\
&\left.-\sum_{i=1}^{k}\binom{k}{i}\partial_r^i R\cdot\partial_r^{k-i+1}\psi - \sum_{i=1}^{k}\binom{k}{i}r^2\partial_r^i r^{-2}\cdot\Delta\!\!\!\!/\,\partial_r^{k-i}\psi\right] L_k\left[\partial_r^k\psi\right]\\
=&-\sum_{i=1}^{k}\binom{k}{i}L_k^v\cdot\partial_r^i D\left(\partial_r^{k-i+2}\psi\right)\left(T\partial_r^k\psi\right) - \sum_{i=1}^{k}\binom{k}{i}L_k^v\cdot\partial_r^i\frac{2}{r}\left(T\partial_r^{k-i}\psi\right)\left(T\partial_r^k\psi\right)\\
&-\sum_{i=1}^{k}\binom{k}{i}L_k^v\cdot\partial_r^i R\left(\partial_r^{k-i+1}\psi\right)\left(T\partial_r^k\psi\right) - \sum_{i=1}^{k}\binom{k}{i}L_k^v\cdot r^2\partial_r^i r^{-2}\left(\Delta\!\!\!\!/\,\partial_r^{k-i}\psi\right)\left(T\partial_r^k\psi\right)\\
&-\sum_{i=1}^{k}\binom{k}{i}L_k^r\cdot\partial_r^i D\left(\partial_r^{k-i+2}\psi\right)\left(\partial_r^{k+1}\psi\right) - \sum_{i=1}^{k}\binom{k}{i}L_k^r\cdot\partial_r^i\frac{2}{r}\left(T\partial_r^{k-i}\psi\right)\left(\partial_r^{k+1}\psi\right)\\
&-\sum_{i=1}^{k}\binom{k}{i}L_k^r\cdot\partial_r^i R\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k+1}\psi\right) - \sum_{i=1}^{k}\binom{k}{i}L_k^r\cdot r^2\partial_r^i r^{-2}\left(\Delta\!\!\!\!/\,\partial_r^{k-i}\psi\right)\left(\partial_r^{k+1}\psi\right).
\end{aligned}$$

In order to obtain the sharp result we need the following lemma

Lemma 4.2.1. *Suppose ψ is a solution to the wave equation which is supported on the (fixed) frequency l. Then for all $0\le i\le l-1$ and any positive number ϵ we have*

$$\begin{aligned}
\left|\int_{\mathcal{H}^+}(\partial_r^i\psi)(\partial_r^l\psi)\right| \le& C_\epsilon\sum_{i=0}^{l-1}\int_{\Sigma_0}J_\mu^N[T^i\psi]n^\mu_{\Sigma_0} + C_\epsilon\sum_{i=0}^{l}\int_{\Sigma_0}J_\mu^N[\partial_r^i\psi]n^\mu_{\Sigma_0}\\
&+\epsilon\int_{\Sigma_\tau\cap\mathcal{A}}J_\mu^{L_l}[\partial_r^l\psi]n^\mu_{\Sigma_\tau} + \epsilon\int_{\mathcal{H}^+}(T\partial_r^l\psi)^2,
\end{aligned}$$

where C_ϵ depends on M, l and Σ_0.

Proof. Using Theorem 1 of Section 2 it suffices to estimate the integrals

$$\int_{\mathcal{H}^+}(T\partial_r^j\psi)(\partial_r^l\psi),$$

where $0 \leq j \leq l$. For $0 \leq j \leq l-1$ we have

$$\int_{\mathcal{H}^+} (T\partial_r^j\psi)(\partial_r^l\psi) = \int_{\mathcal{H}^+\cap\Sigma_\tau} (\partial_r^j\psi)(\partial_r^l\psi) - \int_{\mathcal{H}^+\cap\Sigma_0} (\partial_r^j\psi)(\partial_r^l\psi) - \int_{\mathcal{H}^+} (\partial_r^j\psi)(T\partial_r^l\psi).$$

The two boundary integrals can be estimated using the second Hardy inequality of Section 6 of [1]. Regarding the last integral on the right hand side, the Cauchy-Schwarz and Poincaré inequality imply

$$\int_{\mathcal{H}^+} (\partial_r^j\psi)(T\partial_r^l\psi) \leq \int_{\mathcal{H}^+} \frac{1}{\epsilon}\left|\slashed{\nabla}\partial_r^j\psi\right|^2 + \epsilon(T\partial_r^l\psi)^2.$$

For $j = l$, we use that $(T\partial_r^l\psi)(\partial_r^l\psi) = \frac{1}{2}T(\partial_r^l\psi)^2$ and the second Hardy inequality. □

We are now in position to estimate the bulk integrals. We decompose $\psi = \psi_l + \psi_{\geq l+1}$. This is needed in view of the factor $\chi_{\{k=l\}}$ in the statement of the theorem. Note that **everytime we say that an integral can be estimated we mean that can be estimated by terms appearing on the right hand side of** (4.4) **and ϵ's of the spacetime terms appearing on the left.**

Estimate for $\int_{\mathcal{R}} H_i^1\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k+1}\psi\right), i \geq 0$

For $i = 0$ we have $H_0^1 = -kL_k^r D' \geq 0$ and so this coefficient has the "right" sign in (4.5).

For $i \geq 1$ we use integration by parts

$$\begin{aligned}&\int_{\mathcal{R}} H_i^1\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k+1}\psi\right) + \int_{\mathcal{R}}\left(\partial_r H_i^1 + \frac{2}{r}H_i^1\right)\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right) + \int_{\mathcal{R}} H_i^1\left(\partial_r^{k-i+2}\psi\right)\left(\partial_r^{k}\psi\right)\\ &= \int_{\Sigma_0} H_i^1\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_0} - \int_{\Sigma_\tau} H_i^1\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_\tau} - \int_{\mathcal{H}^+} H_i^1\left(\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\mathcal{H}^+}.\end{aligned}$$

From Proposition 12.4.1. of [1] applied (and generalised) for $\partial_r^k\psi$ and the inductive hypothesis all the integrals over $\mathcal{A}$ and Σ_τ can be estimated. It only remains to estimate the integral over $\mathcal{H}^+$ when $i = 1$. In this case, if we apply the Poincaré inequality for the ψ_l component we notice that we need to absorb a good term in the divergence identity for L_k whenever $k = l$. Indeed,

$$\frac{1}{2}\frac{M^2}{l\,(l+1)}H_1^1\,(M) = -\frac{L_k^r\,(M)}{2} \Leftrightarrow k = l \tag{4.8}$$

This implies that we cannot use the Poincaré inequality on $\mathcal{H}^+$ in order to estimate $(\partial_r^l\psi_l)^2$ anymore. That is why we proved Lemma 4.2.1 which we will use for the following integrals. Clearly, for the component $\psi_{\geq l+1}$ we need a fraction of $\left|\slashed{\nabla}\partial_r^l\psi\right|^2$ along $\mathcal{H}^+$ and thus we can take small (epsilon) portions of this term later on.

Estimate for $\int_{\mathcal{R}} H_i^2\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k+1}\psi\right), i \geq 1$

For $i \geq 2$ we use Stokes' theorem

$$\begin{aligned}&\int_{\mathcal{R}} H_i^2\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k+1}\psi\right) + \int_{\mathcal{R}}\left(\partial_r H_i^2 + \frac{2}{r}H_i^2\right)\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right) + \int_{\mathcal{R}} H_i^2\left(T\partial_r^{k-i+2}\psi\right)\left(\partial_r^{k}\psi\right)\\ &= \int_{\Sigma_0} H_i^2\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_0} - \int_{\Sigma_\tau} H_i^2\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_\tau} - \int_{\mathcal{H}^+} H_i^2\left(T\partial_r^{k-i+1}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\mathcal{H}^+}.\end{aligned}$$

Again from Proposition 12.4.1. of [1] and the inductive hypothesis we can estimate all the above integrals. Note that in order to estimate the integrals along $\mathcal{H}^+$ for the component ψ_l we follow the same argument as in the proof of Lemma 4.2.1. For $i=1$ we use the wave equation and thus

$$\begin{aligned}H_1^2\left(T\partial_r^k\psi\right)\left(\partial_r^{k+1}\psi\right)=&H_1^2\left[\partial_r^{k-1}\left(-D\partial_r^2\psi-\frac{2}{r}T\psi-R\partial_r\psi-\slashed{\Delta}\psi\right)\right]\left(\partial_r^{k+1}\psi\right)\\=&-\sum_{j=0}^{k-1}\binom{k-1}{j}H_1^2\partial_r^jD\left(\partial_r^{k-j+1}\psi\right)\left(\partial_r^{k+1}\psi\right)\\&-\sum_{j=0}^{k-1}\binom{k-1}{j}H_1^2\partial_r^j\frac{2}{r}\left(T\partial_r^{k-j-1}\psi\right)\left(\partial_r^{k+1}\psi\right)\\&-\sum_{j=0}^{k-1}\binom{k-1}{j}H_1^2\partial_r^jR\left(\partial_r^{k-j}\psi\right)\left(\partial_r^{k+1}\psi\right)\\&-H_1^2\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k+1}\psi\right).\end{aligned}$$

The integrals of the first sum can be estimated for $j=0,1$ since their coefficients vanish on the horizon and the case $j\geq 2$ was investigated above.

The integrals of the second sum were also estimated before.

For $j=0$ the integral of the third sum can be estimated since its coefficient vanishes on $\mathcal{H}^+$. If $j\geq 1$ then again these integrals have been estimated. It remains to estimate the integral of the last term. Integration by parts gives

$$\begin{aligned}&\int_{\mathcal{R}}H_1^2\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k+1}\psi\right)+\int_{\mathcal{R}}\left(\partial_rH_1^2+\frac{2}{r}H_1^2\right)\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)+\int_{\mathcal{R}}H_1^2\left(\partial_r^{k}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)\\=&\int_{\Sigma_0}H_1^2\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_0}-\int_{\Sigma_\tau}H_1^2\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\Sigma_\tau}-\int_{\mathcal{H}^+}H_1^2\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)\partial_r\cdot n_{\mathcal{H}^+}.\end{aligned}$$

If we set $Q=\partial_rH_1^2+\frac{2}{r}H_1^2$ then

$$\begin{aligned}\int_{\mathcal{R}}Q\left(\partial_r^{k-1}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)=&\int_{\mathcal{R}}Q\left(\slashed{\Delta}\partial_r^{k-1}\psi-\left[\slashed{\Delta},\partial_r^{k-1}\right]\psi\right)\left(\partial_r^{k}\psi\right)\\=&\int_{\mathcal{R}}Q\left(\slashed{\Delta}\partial_r^{k-1}\psi+\sum_{n=1}^{k-1}\binom{k-1}{n}r^2\partial_r^nr^{-2}\cdot\slashed{\Delta}\partial_r^{k-1-n}\psi\right)\left(\partial_r^{k}\psi\right).\end{aligned}$$

We estimate this integral by applying Stokes' theorem on $\mathbb{S}^2$ and Cauchy-Schwarz and using the inductive hypothesis. Regarding the last bulk integral we have

$$\begin{aligned}\int_{\mathcal{R}}H_1^2\left(\partial_r^{k}\slashed{\Delta}\psi\right)\left(\partial_r^{k}\psi\right)=&\int_{\mathcal{R}}H_1^2\left(\slashed{\Delta}\partial_r^{k}\psi-\left[\slashed{\Delta},\partial_r^{k}\right]\psi\right)\left(\partial_r^{k}\psi\right)\\=&\int_{\mathcal{R}}H_1^2\left(\slashed{\Delta}\partial_r^{k}\psi+\sum_{n=1}^{k}\binom{k}{n}r^2\partial_r^nr^{-2}\slashed{\Delta}\partial_r^{k-n}\psi\right)\left(\partial_r^{k}\psi\right).\end{aligned}$$

Therefore, by applying Stokes' theorem on $\mathbb{S}^2$ we see that this integral can be estimated provided we have $H_1^2<-\frac{1}{2}\partial_rL_k^r\left(M\right)$. Note that H_1^2 does not depend on $\partial_rL_k^r$. Furthermore, the boundary integral over $\mathcal{H}^+$ can be estimated as follows: For the component ψ_l we have $\slashed{\Delta}\psi_l=-\frac{l(l+1)}{r^2}\psi_l$ and thus $\partial_r^{k-1}\slashed{\Delta}\psi_l$ depends on $\partial_r^i\psi_l$ for $0\leq i\leq k-1$ and thus we use Lemma 4.2.1. For the component $\psi_{\geq l+1}$ we commute ∂_r^{k-1} and $\slashed{\Delta}$, we use Stokes' theorem on $\mathbb{S}^2$ and Cauchy-Schwarz as above.

Estimate for $\int_{\mathcal{R}}H_i^3\left(\partial_r^{k-i+2}\psi\right)\left(T\partial_r^k\psi\right), i\geq 1$

The case $i=1$ was investigated above.

For $i\geq 2$ we use Proposition 12.4.1. of [1] and Cauchy-Schwarz.

Estimate for $\int_{\mathcal{R}}H_i^4\left(T\partial_r^{k-i}\psi\right)\left(T\partial_r^k\psi\right), i\geq 1$

We use Cauchy-Schwarz and the inductive hypothesis.

$$\textbf{Estimate for } \int_{\mathcal{R}} H_i^5 \left(\not\Delta \partial_r^i \psi\right)\left(T\partial_r^k\psi\right), i \leq k-1$$

For $i=0$ we solve with respect to $\not\Delta\psi$ in the wave equation and then use Cauchy-Schwarz and the inductive hypothesis. We proceed by induction on i. Assuming that $(\not\Delta\partial_r^j\psi)(T\partial_r^k\psi)$ is estimated for all $0 \leq j \leq i-1$ we will prove that the integral $(\not\Delta\partial_r^i\psi)(T\partial_r^k\psi)$ can also be estimated. We have

$$\not\Delta\partial_r^i\psi\left(T\partial_r^k\psi\right) = \partial_r^i\not\Delta\psi\left(T\partial_r^k\psi\right) + [\not\Delta, \partial_r^i]\psi\left(T\partial_r^k\psi\right)$$

The first term on the right hand side can be estimated by solving with respect to $\not\Delta\psi$ in the wave equation and using Cauchy-Schwarz. The second term can be estimated by our inductive hypothesis.

$$\textbf{Estimate for } \int_{\mathcal{R}} H_i^6 \left(\not\Delta \partial_r^{k-i} \psi\right)\left(\partial_r^{k+1}\psi\right), i \geq 1$$

Integration by parts yields

$$\begin{aligned}
&\int_{\mathcal{R}} H_i^6\left(\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^{k+1}\psi\right) + \int_{\mathcal{R}}\left(\partial_r H_i^6 + \frac{2}{r}H_i^6\right)\left(\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^k\psi\right) + \int_{\mathcal{R}} H_i^6\left(\partial_r\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^k\psi\right)\\
&= \int_{\Sigma_0} H_i^6\left(\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^k\psi\right)\partial_r\cdot n_{\Sigma_0} - \int_{\Sigma_\tau} H_i^6\left(\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^k\psi\right)\partial_r\cdot n_{\Sigma_\tau}\\
&\quad - \int_{\mathcal{H}^+} H_i^6\left(\not\Delta\partial_r^{k-i}\psi\right)\left(\partial_r^k\psi\right)\partial_r\cdot n_{\mathcal{H}^+}.
\end{aligned}$$

The second bulk integral and the boundary integrals over Σ are estimated using Stokes' theorem on $\mathbb{S}^2$ and the inductive hypothesis. The last bulk integral is estimated by commuting the spherical Laplacian with ∂_r and applying again Stokes' theorem on $\mathbb{S}^2$ and Cauchy-Schwarz. Thus for $i \geq 2$ we use the inductive hypothesis and for $i=1$ it suffices to have $H_1^6 < -\frac{1}{2}\partial_r L_k^r(M)$. Regarding the integral over $\mathcal{H}^+$ we have the following: For the component ψ_l we have $\not\Delta\psi_l = -\frac{l(l+1)}{r^2}\psi_l$ and thus $\not\Delta\partial_r^{k-i}\psi_l = -\frac{l(l+1)}{r^2}\partial_r^{k-i}\psi_l$ and so we apply Lemma 4.2.1 to estimate it. For the component $\psi_{\geq l+1}$ we use Stokes' theorem on $\mathbb{S}^2$, Cauchy-Schwarz and the inductive hypothesis.

The construction of L_k is now clear for all $k \in \mathbb{N}$. It suffices to take $L_k^r(M) < 0$, $L_k^v(M) > 0$ and $-\partial_r L_k^r$ and $\partial_r L_k^v(M)$ sufficiently large.

Note that no commutation with the generators of the Lie algebra so(3) is required.

□

4.3. **Improved L^2 Estimates for $T^m\psi, m \geq 1$.** We next show how to apply the results of Section 3 to obtain improved results for $T^m\psi, m \geq 1$. We show the following

Proof of Theorem 2, statement (2). Recall that the only reason we had to restrict k to be such that $k \leq l$ is for estimating the integral $\int_{\mathcal{R}} H_1^1(\partial_r^k\psi)(\partial_r^{k+1}\psi)$. Specifically, we saw that this integral can be controlled by other "good" terms in the energy indentity (4.5) only if $k \leq l$ since in this case we can estimate the integral

$$I_k[\psi] = \int_{\mathcal{H}^+}(\partial_r^k\psi)^2$$

using the Poincaré inequality. Clearly, if we could show that the integral I is bounded, then no use of the Poincaré inequality would be required and thus by working as in Section 4.2 we could derive L^2 estimates for even higher derivatives of ψ. We first prove the following

Lemma 4.3.1. *There exist constants C which depend on M, k, l, m such that for all solutions ψ of the wave equation which are supported on the frequency l we have*

(1)
$$I_k[T\psi] \leq C\sum_{i=0}^{k-1}\int_{\Sigma_0} J_\mu^N[T^i\psi]n_{\Sigma_0}^\mu + C\sum_{i=0}^{k-1}\int_{\Sigma_0\cap\mathcal{A}} J_\mu^N[\partial_r^i\psi]n_{\Sigma_0}^\mu,$$

for all $1 \leq k \leq l$.

(2)
$$I_{l+1}[T\psi]\leq C\sum_{i=0}^{l-1}\int_{\Sigma_0}J^N_{\mu}[T^i\psi]n^{\mu}_{\Sigma_0}+C\sum_{i=0}^{l-1}\int_{\Sigma_0\cap\mathcal{A}}J^N_{\mu}[\partial_r^i\psi]n^{\mu}_{\Sigma_0}.$$

(3)
$$I_{l+m}[T^m\psi]\leq C\sum_{i=0}^{l+m-2}\int_{\Sigma_0}J^N_{\mu}[T^i\psi]n^{\mu}_{\Sigma_0}+C\sum_{i=0}^{l-1}\sum_{j=0}^{m-1}\int_{\Sigma_0\cap\mathcal{A}}J^N_{\mu}[\partial_r^iT^j\psi]n^{\mu}_{\Sigma_0}.$$

Proof. First note that $I_0[T\psi]\leq\int_{\Sigma_0}J^N_{\mu}[\psi]n^{\mu}_{\Sigma_0}$. For $k=1$ (and so $l\geq 1$) we use $\Box_g\psi=0$ and that the zeroth order term can be bounded using the Poincaré inequality to obtain $I_1[T\psi]\leq C\int_{\Sigma_0}J^N_{\mu}[\psi]n^{\mu}_{\Sigma_0}$. For $k=2$ (and so $l\geq 2$) using $\partial_r(\Box_g\psi)=0$ we have that $\partial_r^2T\psi$ can be expressed as a linear combination of $\partial_rT\psi,\partial_r\psi,T\psi,\psi$ on $\mathcal{H}^+$. Note that (the integral of) $\partial_rT\psi,T\psi,\psi$ can be estimated using previous results. The term $\partial_r\psi$ can be estimated using the first statement of Theorem 2. Inductively, using $\partial_r^{k-1}(\Box_g\psi)=0$ (see (3.5)) we obtain

$$I_k[T\psi]\leq C\sum_{i=0}^{k-1}\int_{\mathcal{H}^+}(\partial_r^i\psi)^2+C\sum_{i=0}^{k-1}I_i[T\psi].$$

The first part follows from the inductive hypothesis and the first statement of Theorem 2 (as long as $k\leq l$).

For the critical case of the second part note that for $l=0$ we have $\partial_rT\psi=-\frac{1}{M}T\psi$ on $\mathcal{H}^+$ and so $I_1[T\psi]\leq\int_{\Sigma_0}J^N_{\mu}[\psi]n^{\mu}_{\Sigma_0}$. On the other hand, for $l\geq 1$, since $H_l[T\psi]=0$, we have that $\partial_r^{l+1}T\psi$ can be written as a linear combination of $\partial_r^iT\psi, i=0,1,...,l$ on $\mathcal{H}^+$. Therefore, the first part and the Cauchy-Schwarz inequality finish the proof of the second part.

The third part can be proved by induction on m. For $m=1$ the result has been proved. By considering now (3.5) for $k=l+m-1$ and ψ replaced with $T^{m-1}\psi$ we take that $\partial_r^{l+m}T^m\psi$ can be written (on $\mathcal{H}^+$) as a linear combination of $\partial_r^{l+m-1}T^m\psi$, $\partial_r^{l+m-1}T^{m-1}\psi$ and other lower order terms. The integral of $\partial_r^{l+m-1}T^{m-1}\psi$ can be estimated inductively. Finally, for the term $\partial_r^{l+m-1}T^m\psi$ we observe that $I_{l+m-1}[T^m\psi]=I_{l+m-1}[T^{m-1}(T\psi)]$, which can also be estimated inductively. Note that in view of Proposition 3.1.1 no such estimate holds for $I_k[T^m\psi]$ for $k\geq l+m+1$. □

We can now show that $I_k[T^m\psi]$ is bounded whenever $m\geq 1$ and $k\leq l+m$. Indeed, if $k\leq l$ then $I_k[T^m\psi]=I_k[T(T^{m-1}\psi)]$ and the result follows from the first part of Lemma 4.3.1. If $l\leq k\leq l+m$ then

$$I_k[T^m\psi]=I_{l+m-i}[T^{m-i}(T^i\psi)]=I_{l+m'}[T^{m'}(T^i\psi)],$$

which can also be estimated using Lemma 4.3.1 since $m'=m-i\geq 1$.

Finally, we need to show that $I_k[T^m\psi], k\leq l+m$, is bounded for all $\psi_{\geq l}$ which are supported on frequencies greater or equal to l. Indeed, if $k\leq l$ then we simply use the first statement of Theorem 2. If $k>l$ then

$$I_k[T^m\psi_{\geq l}]=I_k[T^m\psi_l]+I_k[T^m\psi_{l+1}]+\cdots+I_k[T^m\psi_k]+I_k[T^m\psi_{\geq k+1}]$$

The last term on the right hand side can be bounded using Theorem 2 again. The remaining terms can be estimated using the above results. Therefore, no use of the flux of L_k along $\mathcal{H}^+$ is needed whenever $m\geq 1$.

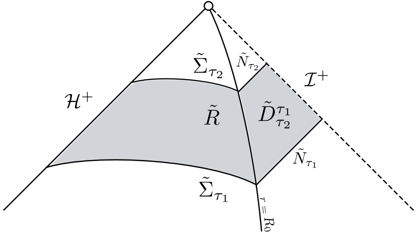
□

5. Energy Decay

In this section we derive the decay for the non-degenerate energy flux of N through an appropriate foliation. The first step is to obtain non degenerate estimates on regions which connect $\mathcal{H}^+$ and $\mathcal{I}^+$ (without containing i^0; this has to do with the fact that energy is radiated away through null infinity). Such estimates were first derived in the recent [16] along with a new robust method for obtaining decay results. Here we establish several estimates which will allow us to adapt the methods of [16] in the extreme case. These new estimates are closely related with the trapping properties of $\mathcal{H}^+$.

Recall the $\tilde{\Sigma}_\tau$ foliation defined in Section 2. For arbitrary $\tau_1 < \tau_2$ we define

$$\tilde{\mathcal{R}}^{\tau_2}_{\tau_1} = \cup_{\tau\in[\tau_1,\tau_2]}\tilde{\Sigma}_\tau,\ \tilde{\mathcal{D}}^{\tau_2}_{\tau_1} = \tilde{\mathcal{R}}^{\tau_2}_{\tau_1} \cap \{r \geq R_0\},\ \tilde{N}_\tau = \tilde{\Sigma}_\tau \cap \{r \geq R_0\},\ \Delta^{\tau_2}_{\tau_1} = \tilde{\mathcal{R}}^{\tau_2}_{\tau_1} \cap \{r = R_0\}.$$



5.1. **r-Weighted Energy Estimates in a Neighbourhood of $\mathcal{I}^+$.** The main idea is to derive a non-degenerate L^2 spacetime estimate and then derive similar estimates for its boundary terms. From now on we work with the null (u, v) coordinates unless otherwise stated.

Proposition 5.1.1. *Suppose $p < 3$. There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that if ψ satisfies the wave equation and $\phi = r\psi$ then*

$$\begin{aligned}&\int_{\tilde{N}_{\tau_2}} r^p \frac{(\partial_v\phi)^2}{r^2} + \int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} r^{p-1}(p+2)\frac{(\partial_v\phi)^2}{r^2} + \int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} \frac{r^{p-1}}{4}(-pD - rD')\left|\nabla\!\!\!\!/\,\psi\right|^2 \\ &\leq C\int_{\tilde{\Sigma}_{\tau_1}} J^T_\mu[\psi]\, n^\mu_{\tilde{\Sigma}_{\tau_1}} + \int_{\tilde{N}_{\tau_1}} r^p\frac{(\partial_v\phi)^2}{r^2}\end{aligned} \tag{5.1}$$

Proof. We first consider the cut-off function $\zeta : [R_0, +\infty) \to [0, 1]$ such that

$$\zeta(r) = 0 \text{ for all } r \in [R_0, R_0 + 1/2],\ \zeta(r) = 1 \text{ for all } r \in [R_0 + 1, +\infty).$$

Let $q = p - 2$. We consider the vector field

$$V = r^q\partial_v$$

which we apply as multiplier acting on the function $\zeta\phi$ in the region $\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}$. Then

$$\int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} K^V[\zeta\phi] + \mathcal{E}^V[\zeta\phi] = \int_{\partial\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} J^V_\mu[\zeta\phi]n^\mu.$$

Note that for $r \geq R_0 + 1$ we have $K^V[\zeta\phi] = K^V[\phi]$ and $\mathcal{E}^V[\zeta\phi] = \mathcal{E}^V[\phi]$. Then,

$$\begin{aligned}K^V(\phi) &= \mathbf{T}_{\mu\nu}\left(\nabla^\mu\left(r^q\partial_v\right)\right)^\nu = \mathbf{T}_{\mu\nu}\left(\left(\nabla^\mu r^q\right)\partial_v\right)^\nu + \mathbf{T}_{\mu\nu}r^q\left(\nabla^\mu\partial_v\right)^\nu \\ &= 2r^{q-1}(\partial_u\phi)(\partial_v\phi) + qr^{q-1}(\partial_v\phi)^2 + \frac{r^{q-1}}{4}(-qD - rD')\left|\nabla\!\!\!\!/\,\phi\right|^2.\end{aligned}$$

Note that since ψ solves the wave equation ϕ satisfies $\frac{4}{D}\partial_u\partial_v\phi + \frac{D'}{r}\phi - \Delta\!\!\!\!/\,\phi = 0$ and so

$$\Box_g\phi = -\frac{2}{r}(\partial_u\phi - \partial_v\phi) + \frac{D'}{r}\phi,$$

which, as expected, depends only on the 1-jet of ϕ. Therefore,

$$\mathcal{E}^V[\phi] = r^q(\partial_v\phi)(\Box_g\phi) = -2r^{q-1}(\partial_u\phi)(\partial_v\phi) + 2r^{q-1}(\partial_v\phi)^2 + D'r^{q-1}\phi(\partial_v\phi).$$

Thus

$$K^V[\phi] + \mathcal{E}^V[\phi] = (q+2)r^{q-1}(\partial_v\phi)^2 + \frac{r^{q-1}}{4}(-qD - rD')\left|\nabla\!\!\!\!/\,\phi\right|^2 + D'r^{q-1}\phi(\partial_v\phi).$$

However,

$$\int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} D' r^{q-1} \zeta\phi \left(\partial_v \zeta\phi\right) = \int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} r^{q-4} \frac{M}{2} D \left[\sqrt{D}(1-q) - \frac{3M}{r}\right] (\zeta\phi)^2$$
$$- \int_{\Delta_{\tau_1}^{\tau_2}} \frac{r^{q-1}}{4} D' \sqrt{D} \, (\zeta\phi)^2 + \int_{\mathcal{I}^+} \frac{D'D}{4} r^{q-1} \, (\zeta\phi)^2.$$

Note that in Minkowski spacetime we would have no zeroth order term in the wave equation. In our case we do have, in such a way, however, such that the terms on the right hand side of the above identity have the right sign for $p < 3$ and sufficiently large[2] R_0.

In view of the cut-off function ζ all the integrals over $\Delta_{\tau_1}^{\tau_2}$ vanish. Clearly, all error terms that arise in the region[3] $\mathcal{W} = \overline{\operatorname{supp}(\zeta - 1)} = \{R_0 \leq r \leq R_0 + 1\}$ are quadratic forms of the 1-jet of ψ and, therefore, these integrals are bounded by $\int_{\tilde{\Sigma}_{\tau_1}} J_\mu^T[\psi] \, n_{\tilde{\Sigma}_{\tau_1}}^\mu$. Note that only a degenerate Morawetz (see [1]) is needed for the considerations near null unfinity. Also

$$\int_{\partial\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} J_\mu^V[\zeta\phi] n^\mu = \int_{\tilde{N}_{\tau_1}} r^q \left(\partial_v \zeta\phi\right)^2 - \int_{\tilde{N}_{\tau_2}} r^q \left(\partial_v \zeta\phi\right)^2 - \int_{\mathcal{I}^+} \frac{D}{4} \left|\nabla\!\!\!\!/\,\phi\right|^2.$$

The last two integrals on the right hand side appear with the right sign. Finally, in view of the first Hardy inequality of Section 6 of [1], the error terms produced by the cut-off ζ in the region $\mathcal{W}$ are controlled by the flux of T through $\tilde{\Sigma}_{\tau_1}$.

□

The reason we introduced the function ϕ is because the weight r that it contains makes it non-degenerate ($\psi = 0$ on $\mathcal{I}^+$ but ϕ does not vanish there in general). The reason we have divided by r^2 in (5.1) is because we want to emphasise the weight that corresponds to ψ and not to ϕ.

A first application of the above r-weighted energy estimate is the following

Proposition 5.1.2. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that if ψ satisfies the wave equation and $\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}$ as defined above with R_0 sufficiently large, then*

$$\int_{\tau_1}^{\tau_2} \left(\int_{\tilde{N}_\tau} J_\mu^T[\psi] n_{\tilde{N}_\tau}^\mu \right) d\tau \leq C \int_{\tilde{\Sigma}_{\tau_1}} J_\mu^T[\psi] \, n_{\tilde{\Sigma}_{\tau_1}}^\mu + C \int_{\tilde{N}_{\tau_1}} r^{-1} \left(\partial_v \phi\right)^2.$$

Proof. Applying Proposition 5.1.1 for $p = 1$ and using the fact that for $r \geq R_0$ and R_0 large enough $D - rD' > \frac{1}{2}$, we have that there exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that

$$\int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{r^2} \left(\partial_v \phi\right)^2 + \frac{1}{r^2} \left|\nabla\!\!\!\!/\,\phi\right|^2 \leq C \int_{\tilde{\Sigma}_{\tau_1}} J_\mu^T[\psi] \, n_{\tilde{\Sigma}_{\tau_1}}^\mu + C \int_{\tilde{N}_{\tau_1}} r^{-1} \left(\partial_v \phi\right)^2. \tag{5.2}$$

Note now that since $\left|\nabla\!\!\!\!/\,\phi\right|^2 = r^2 \left|\nabla\!\!\!\!/\,\psi\right|^2$, (5.2) yields

$$\int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \left|\nabla\!\!\!\!/\,\psi\right|^2 \leq C \int_{\tilde{\Sigma}_{\tau_1}} J_\mu^T[\psi] \, n_{\tilde{\Sigma}_{\tau_1}}^\mu + C \int_{\tilde{N}_{\tau_1}} r^{-1} \left(\partial_v \phi\right)^2.$$

Furthermore, for sufficiently large R_0 we have

$$\int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{r^2} \left(\partial_v \phi\right)^2 \geq \int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{2D^2 r^2} \left(\partial_v \phi\right)^2 = \int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{2D^2} \left(\partial_v \psi\right)^2 + \int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{4Dr^2} \partial_v (r\psi^2).$$

However, if ζ is the cut-off function introduced in the proof of Proposition 5.1.1, then

$$\int_{\tilde{\mathcal{D}}_{\tau_1}^{\tau_2}} \frac{1}{4Dr^2} \partial_v \left(r(\zeta\psi)^2\right) = \int_{\mathcal{I}^+} \frac{1}{8r} (\zeta\psi)^2.$$

Therefore, the above integral is of the right sign modulo some error terms in the region $\mathcal{W}$ coming from the cut-off ζ. These terms are quadratic in the 1-jet of ψ and so can be controlled by the T-flux.

---

[2] Clearly we need to take $R_0 > 2M$.

[3] The weights in r play no role in this region.

Finally, since $n^\mu_{\tilde{N}_\tau}$ is null we have $J^T_\mu[\psi]n^\mu_{\tilde{N}_\tau} \sim (\partial_v\psi)^2 + |\slashed{\nabla}\psi|^2$ and thus by (5.2) and the coarea formula we have the required result. □

This is a spacetime estimate which does **not** degenerate at infinity. Note the importance of the fact that the region $\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}$ does not contain i^0! If we are to obtain the full decay for the energy, then we need to prove decay for the boundary terms in Proposition 5.1.2. The first step is to derive a spacetime estimate of the r-weighted quantity $r^{-1}(\partial_v\phi)^2$.

Proposition 5.1.3. *There exists a constant C which depends on M and $\tilde{\Sigma}_0$ such that*

$$\int_{\tau_1}^{\tau_2}\left(\int_{\tilde{N}_\tau} r^{-1}(\partial_v\phi)^2\right)d\tau \ \le C\int_{\tilde{\Sigma}_{\tau_1}} J^T_\mu\left[\psi\right] n^\mu_{\tilde{\Sigma}_{\tau_1}} + C\int_{\tilde{N}_{\tau_1}}(\partial_v\phi)^2.$$

Proof. Appying the r-weighted energy estimate for $p=2$ we obtain

$$\begin{aligned}\int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} r^{-1}(\partial_v\phi)^2 \ &\le \int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} \frac{M\sqrt{D}}{4r^2}\left|\slashed{\nabla}\phi\right|^2 + C\int_{\tilde{\Sigma}_{\tau_1}} J^T_\mu\left[\psi\right] n^\mu_{\tilde{\Sigma}_{\tau_1}} + C\int_{\tilde{N}_{\tau_1}}(\partial_v\phi)^2\\ &\le C\int_{\tilde{\mathcal{D}}^{\tau_2}_{\tau_1}} \frac{1}{r^2}\left|\slashed{\nabla}\phi\right|^2 + C\int_{\tilde{\Sigma}_{\tau_1}} J^T_\mu\left[\psi\right] n^\mu_{\tilde{\Sigma}_{\tau_1}} + C\int_{\tilde{N}_{\tau_1}}(\partial_v\phi)^2.\end{aligned}$$

The result now follows from (5.2) and the coarea formula. □

5.2. **Integrated Decay of Local (Higher Order) Energy.** We have shown in [1] that in order to obtain a non-degenerate spacetime estimate near $\mathcal{H}^+$ we need to commute the wave equation with the transversal to the horizon vector field ∂_r and assume that the zeroth spherical harmonic vanishes. Indeed, if $\mathcal{A}$ is a spatially compact neighbourhood of $\mathcal{H}^+$ (which may contain the photon sphere) then we have:

Proposition 5.2.1. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that if ψ satisfies the wave equation and is supported on $l\geq 1$, then*

$$\int_{\tau_1}^{\tau_2}\left(\int_{\mathcal{A}\cap\tilde{\Sigma}_\tau} J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau \ \le C\int_{\tilde{\Sigma}_{\tau_1}} J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau} + C\int_{\tilde{\Sigma}_{\tau_1}} J^N_\mu[T\psi]n^\mu_{\tilde{\Sigma}_\tau} + C\int_{\mathcal{A}\cap\tilde{\Sigma}_{\tau_1}} J^N_\mu[\partial_r\psi]n^\mu_{\tilde{\Sigma}_\tau}.$$

Regarding the above boundary terms we have

Proposition 5.2.2. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that if ψ satisfies the wave equation and is supported on $l\geq 2$, then*

$$\int_{\tau_1}^{\tau_2}\left(\int_{\mathcal{A}\cap\tilde{\Sigma}_\tau} J^N_\mu[\partial_r\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau \ \le C\sum_{i=0}^{2}\int_{\tilde{\Sigma}_{\tau_1}} J^N_\mu[T^i\psi]n^\mu_{\tilde{\Sigma}_\tau} + C\sum_{k=1}^{2}\int_{\mathcal{A}\cap\tilde{\Sigma}_{\tau_1}} J^N_\mu[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_\tau}.$$

Proof. Immediate from Theorem 2 of Section 2 and the coarea formula. □

5.3. **Weighted Energy Estimates in a Neighbourhood of $\mathcal{H}^+$.** Since for $l=0$ the above estimates do not hold for generic initial data, we are left proving decay for the degenerate energy. For this we derive a hierarchy of (degenerate) energy estimates in a neighbourhood of $\mathcal{H}^+$, the crucial ingredient of which is the existence of the vector field P. This vector field is timelike in the domain of outer communications and becomes null on the horizon “linearly”. This linearity allows P to capture the degenerate redshift in $\mathcal{A}$ in a weaker way than N but in stronger way than T. In this subsection, we use the (v,r) coordinates.

Proposition 5.3.1. *There exists a φ^T_τ-invariant causal vector field P and a constant C which depends only on M such that for all ψ we have*

$$J^T_\mu[\psi]n^\mu_\Sigma \le CK^P[\psi], \quad J^P_\mu[\psi]n^\mu_\Sigma \le CK^{N,\delta,-\frac{1}{2}}[\psi]$$

in an appropriate neighbourhood $\mathcal{A}$ of $\mathcal{H}^+$.

Proof. Let our ansatz be $P=P^vT+P^r\partial_r$. Recall that

$$K^P[\psi]=F_{vv}\left(T\psi\right)^2+F_{rr}\left(\partial_r\psi\right)^2+F_{\nabla\!\!\!/}\left|\nabla\!\!\!/\psi\right|^2+F_{vr}\left(T\psi\right)\left(\partial_r\psi\right),$$

where the coefficients are given by

$$F_{vv}=\left(\partial_rP^v\right),\ F_{rr}=D\left[\frac{\left(\partial_rP^r\right)}{2}-\frac{P^r}{r}\right]-\frac{P^rD'}{2},\ F_{\nabla\!\!\!/}=-\frac{1}{2}\left(\partial_rP^r\right),\ F_{vr}=D\left(\partial_rP^v\right)-\frac{2P^r}{r}.$$

Let us take $P^r(r)=-\sqrt{D}$ for $M\leq r\leq r_0<2M$ with r_0 to be determined later. Then

$$F_{rr}=D\left[-\frac{D'}{4\sqrt{D}}+\frac{\sqrt{D}}{r}\right]+\frac{\sqrt{D}D'}{2}=D\left[\frac{D'}{4\sqrt{D}}+\frac{\sqrt{D}}{r}\right]\sim D.$$

Since $\frac{D'}{4\sqrt{D}}=\frac{M}{2r^2}$, the constants in $\sim$ depend on M and the choice for r_0. Also,

$$F_{vr}=\sqrt{D}\left[\sqrt{D}(\partial_rP^v)+\frac{2}{r}\right]\leq\epsilon D+\frac{1}{\epsilon}\left[\sqrt{D}(\partial_rP^v)+\frac{2}{r}\right]^2.$$

If we take ϵ sufficiently small and P^v such that $\frac{1}{\epsilon}\left[\sqrt{D}(\partial_rP^v)+\frac{2}{r}\right]^2<\partial_rP^v$ (note that this is always possible in view of the degeneracy of $\sqrt{D}$ at $\mathcal{H}^+$), then there exists $r_0>M$ such that

$$K^P[\psi]\sim\left((T\psi)^2+D(\partial_r\psi)^2+|\nabla\!\!\!/\psi|^2\right)\sim J^T_\mu[\psi]n^\mu_\Sigma \tag{5.3}$$

in $\mathcal{A}=\{M\leq r\leq r_0\}$. Extend now P in $\mathcal{R}$ such that $P^v(r)=1$ and $P^r(r)=0$ for all $r\geq r_1>r_0$ for some $r_1<2M$. This proves the first part of the proposition. In region $\mathcal{A}$ we have $-g(P,P)\sim\sqrt{D}$ and so

$$J^P_\mu[\psi]n^\mu_\Sigma\sim(T\psi)^2+\sqrt{D}(\partial_r\psi)^2+|\nabla\!\!\!/\psi|^2\sim K^{N,\delta,-\frac{1}{2}}[\psi]. \tag{5.4}$$

□

5.4. **Decay of Degenerate Energy.**

5.4.1. *Uniform Boundedness of P-Energy.*

First we need to prove that the P-flux is uniformly bounded.

Proposition 5.4.1. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that for all solutions ψ of the wave equation we have*

$$\int_{\tilde{\Sigma}_\tau}J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq C\int_{\tilde{\Sigma}_0}J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_0}. \tag{5.5}$$

Proof. Stokes' theorem for the current J^P_μ gives us

$$\int_{\tilde{\Sigma}_\tau}J^P_\mu n^\mu+\int_{\mathcal{H}^+}J^P_\mu n^\mu+\int_{\mathcal{I}^+}J^P_\mu n^\mu+\int_{\tilde{\mathcal{R}}}K^P=\int_{\tilde{\Sigma}_0}J^P_\mu n^\mu.$$

Note that since P is a future-directed causal vector field, the boundary integrals over $\mathcal{H}^+$ and $\mathcal{I}^+$ are non-negative. The same also holds for K^P in region $\mathcal{A}$ whereas it vanishes away from the horizon. In the intermediate region this spacetime integral can be bounded using the degenerate X estimate of Theorem 1 of [1]. The result now follows from $J^T_\mu n^\mu\leq CJ^P_\mu n^\mu$. □

We are now in a position to derive local integrated decay for the T-energy.

Proposition 5.4.2. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that for all solutions ψ of the wave equation we have*

$$\int_{\tau_1}^{\tau_2}\left(\int_{\mathcal{A}\cap\tilde{\Sigma}_\tau}J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau\leq C\int_{\tilde{\Sigma}_{\tau_1}}J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\tau_1}}$$

and

$$\int_{\tau_1}^{\tau_2}\left(\int_{\mathcal{A}\cap\tilde{\Sigma}_\tau} J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau \leq C\int_{\tilde{\Sigma}_{\tau_1}} J^N_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\tau_1}}$$

in an appropriate φ_τ*-invariant neighbourhood* $\mathcal{A}$ *of* $\mathcal{H}^+$*.*

Proof. From the divergence identity for the current J^P_μ and the boundedness of P-energy we have

$$\int_{\mathcal{A}} K^P \leq C\int_{\tilde{\Sigma}_{\tau_1}} J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\tau_1}}$$

for a uniform constant C. Thus the first estimate follows from (5.3) and the coarea formula. Likewise, the second estimate follows from the divergence identity for the current $J^{N,\delta,-\frac{1}{2}}_\mu$, the boundedness of the non-degenerate N-energy and (5.4). □

5.4.2. *The Dyadic Sequence* ρ_n*.* In view of Propositions 5.1.2 and 5.4.2 we have

$$\int_{\tau_1}^{\tau_2}\left(\int_{\tilde{\Sigma}_\tau} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau \ \leq\ CI^T_{\tilde{\Sigma}_{\tau_1}}[\psi], \tag{5.6}$$

where

$$I^T_{\tilde{\Sigma}_\tau}[\psi] = \int_{\tilde{\Sigma}_\tau} J^P_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau} + \int_{\tilde{\Sigma}_\tau} J^T_\mu[T\psi]n^\mu_{\tilde{\Sigma}_\tau} + \int_{\tilde{N}_\tau} r^{-1}\left(\partial_v\phi\right)^2.$$

Moreover, from Propositions 5.4.2 and 5.1.3 we have

$$\int_{\tau_1}^{\tau_2} I^T_{\tilde{\Sigma}_\tau}[\psi]d\tau \leq CI^T_{\tilde{\Sigma}_{\tau_1}}[T\psi] + C\int_{\tilde{\Sigma}_{\tau_1}} J^N_\mu[\psi]n^\mu + C\int_{\tilde{N}_{\tau_1}} (\partial_v\phi)^2, \tag{5.7}$$

for a constant C that depends on M and $\tilde{\Sigma}_0$. This implies that there exists a dyadic sequence[4] ρ_n such that

$$I^T_{\tilde{\Sigma}_{\rho_n}}[\psi] \leq \frac{E_1}{\rho_n},$$

where E_1 is equal to the right hand side of (5.7) (with $\tau_1 = 0$) and depends only on the initial data of ψ. We have now all the tools to derive decay for the degenerate energy.

Proposition 5.4.3. *There exists a constant* C *that depends on* M *and* $\tilde{\Sigma}_0$ *such that for all solutions* ψ *of the wave equation we have*

$$\int_{\tilde{\Sigma}_\tau} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau} \leq CE_1\frac{1}{\tau^2},$$

where E_1 *is as defined above.*

Proof. We apply (5.6) for the dyadic interval $[\rho_n, \rho_{n+1}]$ to obtain

$$\int_{\rho_n}^{\rho_{n+1}}\left(\int_{\tilde{\Sigma}_\tau} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau}\right)d\tau \ \leq\ CE_1\frac{1}{\rho_n}.$$

In view of the energy estimate

$$\int_{\tilde{\Sigma}_\tau} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_\tau} \ \leq\ C\int_{\tilde{\Sigma}_{\tau'}} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\tau'}},$$

which holds for all $\tau \geq \tau'$, we have

$$(\rho_{n+1}-\rho_n)\int_{\tilde{\Sigma}_{\rho_{n+1}}} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\rho_{n+1}}} \ \leq\ CE_1\frac{1}{\rho_{n+1}}.$$

Since there exists a uniform constant $b > 0$ such that $b\tau_{n+1} \leq \tau_{n+1} - \tau_n$ we have

$$\int_{\tilde{\Sigma}_{\rho_{n+1}}} J^T_\mu[\psi]n^\mu_{\tilde{\Sigma}_{\rho_{n+1}}} \ \leq\ CE_1\frac{1}{\rho^2_{n+1}}.$$

---

[4] Dyadic sequence is an increasing sequence ρ_n such that $\rho_n \sim \rho_{n+1} \sim (\rho_{n+1} - \rho_n)$.

Now, for $\tau\geq\rho_1$ there exists $n\in\mathbb{N}$ such that $\rho_n\leq\tau\leq\rho_{n+1}$. Therefore,

$$\int_{\tilde{\Sigma}_{\tau}}J^T_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\leq C\int_{\tilde{\Sigma}_{\rho_{n+1}}}J^T_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\rho_{n+1}}}\leq\frac{CE_1}{\rho_n^2}\sim\frac{CE_1}{\rho_{n+1}^2}\leq CE_1\frac{1}{\tau^2},$$

which is the required decay result for the T-energy.

□

5.5. **Decay of Non-Degenerate Energy.** We now derive decay for the non-degenerate energy. Note that for obtaining such a result we must use Proposition 5.2.1 which however holds for solutions to the wave equation supported on the frequencies $l\geq 1$. In this case, in view of the previous estimates we have

$$\int_{\tau_1}^{\tau_2}\left(\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\right)d\tau\leq CI^N_{\tilde{\Sigma}_{\tau_1}}[\psi],\tag{5.8}$$

where

$$I^N_{\tilde{\Sigma}_{\tau}}[\psi]=\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}+\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[T\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}+\int_{\mathcal{A}\cap\tilde{\Sigma}_{\tau}}J^N_{\mu}[\partial_r\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}+\int_{\tilde{N}_{\tau}}r^{-1}\left(\partial_v\phi\right)^2.$$

Proposition 5.5.1. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that for all solutions ψ to the wave equation which are supported on $l\geq 1$ we have*

$$\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\leq CE_2\frac{1}{\tau},$$

where E_2 depends only on the initial data of ψ and is equal to the right hand side of (5.8) *(with $\tau_1=0$).*

Proof. We apply (5.8) for the interval $[0,\tau]$ and use the energy estimate

$$\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\leq C\int_{\tilde{\Sigma}_{\tau'}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau'}},$$

which holds for all $\tau\geq\tau'$ and for a uniform constant C. □

5.5.1. *The Dyadic Sequence τ_n.* If we consider solutions ψ which are supported on $l\geq 2$ then from Propositions 5.1.3, 5.2.2 and by commuting (5.8) with T we take

$$\int_{\tau_1}^{\tau_2}I^N_{\tilde{\Sigma}_{\tau}}[\psi]d\tau\leq CI^N_{\tilde{\Sigma}_{\tau_1}}[\psi]+CI^N_{\tilde{\Sigma}_{\tau_1}}[T\psi]+C\int_{\mathcal{A}\cap\tilde{\Sigma}_{\tau_1}}J^N_{\mu}[\partial_r\partial_r\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}+C\int_{\tilde{N}_{\tau_1}}\left(\partial_v\phi\right)^2\tag{5.9}$$

This implies that there exists a dyadic sequence τ_n such that

$$I^N_{\tilde{\Sigma}_{\tau_n}}[\psi]\leq\frac{E_3}{\tau_n},$$

where the constant E_3 is equal to the right hand side of (5.9) (with $\tau_1=0$). We can now derive decay for the non-degenerate energy.

Proposition 5.5.2. *There exists a constant C that depends on M and $\tilde{\Sigma}_0$ such that for all solutions ψ to the wave equation which are supported on $l\geq 2$ we have*

$$\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\leq CE_3\frac{1}{\tau^2},$$

where E_3 is as defined above.

Proof. If we apply (5.8) for the dyadic intervals $[\tau_n,\tau_{n+1}]$ we obtain

$$\int_{\tau_n}^{\tau_{n+1}}\left(\int_{\tilde{\Sigma}_{\tau}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau}}\right)d\tau\leq\frac{CE_3}{\tau_n}.$$

In view of the boundedness of the N-energy we have

$$(\tau_{n+1}-\tau_n)\int_{\tilde{\Sigma}_{\tau_{n+1}}}J^N_{\mu}[\psi]n^{\mu}_{\tilde{\Sigma}_{\tau_{n+1}}}\leq\frac{CE_3}{\tau_{n+1}}.$$

Since there exists a uniform constant $b > 0$ such that $b\tau_{n+1} \leq \tau_{n+1} - \tau_n$ we obtain

$$\int_{\tilde{\Sigma}_{\tau_{n+1}}} J^N_\mu[\psi] n^\mu_{\tilde{\Sigma}_{\tau_{n+1}}} \leq \frac{CE_3}{\tau^2_{n+1}}.$$

Now, for $\tau \geq \tau_1$ there exists $n \in \mathbb{N}$ such that $\tau_n \leq \tau \leq \tau_{n+1}$. Therefore,

$$\int_{\tilde{\Sigma}_\tau} J^N_\mu[\psi] n^\mu_{\tilde{\Sigma}_\tau} \leq \tilde{C} \int_{\tilde{\Sigma}_{\tau_{n+1}}} J^N_\mu[\psi] n^\mu_{\tilde{\Sigma}_{\tau_{n+1}}} \leq \frac{CE_3}{\tau_n^2} \sim \frac{CE_3}{\tau^2_{n+1}} \leq CE_3 \frac{1}{\tau^2}$$

which is the required decay result for the energy.

□

The above propositions completes the proof of Theorem 3.

6. Pointwise Estimates

6.1. **Retrieving Pointwise Boundedness.** In [1] we proved that all the solutions to the wave equation ψ remain uniformly bounded in $\mathcal{M}$. We show the same result here by exploiting the spherical symmetry. We work with the foliation Σ_τ (or $\tilde{\Sigma}_\tau$) and the induced coordinate system (ρ, ω). For $r_0 \geq M$ we have

$$\psi^2(r_0, \omega) = \left(\int_{r_0}^{+\infty} (\partial_\rho \psi)\, d\rho \right)^2 \leq \left(\int_{r_0}^{+\infty} (\partial_\rho \psi)^2 \rho^2 d\rho \right) \left(\int_{r_0}^{+\infty} \frac{1}{\rho^2} d\rho \right) = \frac{1}{r_0} \left(\int_{r_0}^{+\infty} (\partial_\rho \psi)^2 \rho^2 d\rho \right).$$

Therefore,

$$\int_{\mathbb{S}^2} \psi^2(r_0, \omega) d\omega \leq \frac{1}{r_0} \int_{\mathbb{S}^2} \int_{r_0}^{+\infty} (\partial_\rho \psi)^2 \rho^2 d\rho d\omega \leq \frac{C}{r_0} \int_{\Sigma_\tau \cap \{r \geq r_0\}} J^N_\mu[\psi] n^\mu_{\Sigma_\tau}, \tag{6.1}$$

where C is a constant that depends only on M and Σ_0.

Theorem 6.1. *There exists a constant C which depends on M and Σ_0 such that for all solutions ψ of the wave equation we have*

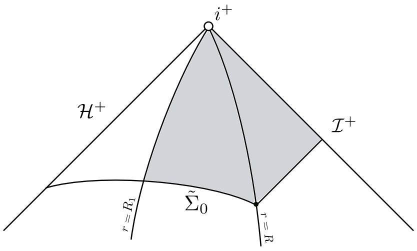
$$|\psi|^2 \leq C \cdot E_4 \frac{1}{r}, \tag{6.2}$$

where $E_4 = \sum_{|k| \leq 2} \int_{\Sigma_0} J^N_\mu[\Omega^k \psi] n^\mu_{\Sigma_0}$.

Proof. From the Sobolev inequality on $\mathbb{S}^2$ we have $|\psi|^2 \leq C \sum_{|k| \leq 2} \int_{\mathbb{S}^2} \left(\Omega^k \psi\right)^2$ and the theorem follows from (6.1) and the uniform boundedness of the non-degenerate energy. □

6.2. **Pointwise Decay.**

6.2.1. *Decay away from $\mathcal{H}^+$.* We consider the region $\{r \geq R_1\}$, where $R_1 > M$. From now on, C will be a constant depending only on M, R_1 and $\tilde{\Sigma}_0$.



Clearly, in this region we have $J^N_\mu n^\mu_\Sigma \sim J^T_\mu n^\mu_\Sigma$ and $\sim$ depends on R_1. Therefore, from (6.1) we have that for any $r \geq R_1$

$$\int_{\mathbb{S}^2} \psi^2(r, \omega) d\omega \leq \frac{C}{r} \int_{\tilde{\Sigma}_\tau} J^T_\mu[\psi] n^\mu_{\tilde{\Sigma}_\tau} \leq C \cdot E_1[\psi] \frac{1}{r \cdot \tau^2}.$$

Applying the above for ψ, $\Omega_i\psi$, $\Omega_{ij}\psi$ and using the Sobolev inequality for $\mathbb{S}^2$ yields

$$\psi^2 \leq CE_5\frac{1}{r\cdot\tau^2},$$

where $E_5 = \sum_{|k|\leq 2}E_1\left[\Omega^k\psi\right]$. Next we improve the decay with respect to r. Observe that for all $r \geq R_1$ we have

$$\begin{aligned}\int_{\mathbb{S}^2}(r\psi)^2(r,\omega)d\omega &= \int_{\mathbb{S}^2}(R_1\psi)^2(R_1,\omega)d\omega + 2\int_{\mathbb{S}^2}\int_{R_1}^{r}\frac{\psi}{\rho}\partial_\rho(\rho\psi)\rho^2 d\rho d\omega\\ &\leq CE_1[\psi]\frac{1}{\tau^2} + C\sqrt{\int_{\tilde{\Sigma}_\tau\cap\{r\geq R_1\}}\frac{1}{\rho^2}\psi^2\int_{\tilde{\Sigma}_\tau\cap\{r\geq R_1\}}\left(\partial_\rho(\rho\psi)\right)^2}.\end{aligned}$$

However, from the first Hardy inequality (see Section 6 of [1]) we have

$$\int_{\tilde{\Sigma}_\tau}\frac{1}{\rho^2}\psi^2 \leq C\int_{\tilde{\Sigma}_\tau}J_\mu^T[\psi]n^\mu_{\tilde{\Sigma}_\tau} \leq CE_1\frac{1}{\tau^2}.$$

Moreover, if R_0 is the constant defined in Section 5 and recalling that $\rho\psi = \phi$ we have

$$\begin{aligned}\int_{\tilde{\Sigma}_\tau\cap\{r\geq R_1\}}\left(\partial_\rho(\rho\psi)\right)^2 &= \int_{\tilde{\Sigma}_\tau\cap\{R_0\geq r\geq R_1\}}\left(\partial_\rho(\rho\psi)\right)^2 + \int_{\tilde{N}_\tau}(\partial_v\phi)^2\\ &\leq C\int_{\tilde{\Sigma}_0}J_\mu^T[\psi]n^\mu_{\tilde{\Sigma}_0} + \int_{\tilde{N}_\tau}(\partial_v\phi)^2 \leq C\int_{\tilde{\Sigma}_0}J_\mu^T[\psi]n^\mu_{\tilde{\Sigma}_0} + \int_{\tilde{N}_0}(\partial_v\phi)^2,\end{aligned}$$

where for the second inequality we used Propositions 5.1.1 and 5.1.2. Hence for $\tau \geq 1$ we have

$$r^2\int_{\mathbb{S}^2}\psi^2(r,\omega)d\omega \leq CE_1\frac{1}{\tau^2} + C\sqrt{E_1}\sqrt{C\int_{\tilde{\Sigma}_0}J_\mu^T[\psi]n^\mu_{\tilde{\Sigma}_0} + \int_{\tilde{N}_0}(\partial_v\phi)^2}\frac{1}{\tau} \leq CE_1\frac{1}{\tau},$$

since the quantitiy in the square root is dominated by E_1. Therefore, by the Sobolev inequality on $\mathbb{S}^2$ we obtain

$$\psi^2 \leq CE_5\frac{1}{r^2\cdot\tau}.$$

6.2.2. *Decay near $\mathcal{H}^+$.* We are now investigating the behaviour of ψ in the region $\{M \leq r \leq R_1\}$. We first prove the following

Lemma 6.2.1. *There exists a constant C which depends only on M such that for all r_1 with $M < r_1$ and all solutions ψ of the wave equation we have*

$$\int_{\mathbb{S}^2}\psi^2(r_1,\omega)d\omega \leq \frac{C}{(r_1-M)^2}\frac{E_1}{\tau^2}.$$

Proof. Using (6.1) we obtain

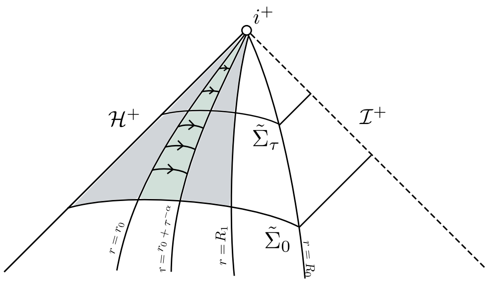
$$\begin{aligned}\int_{\mathbb{S}^2}\psi^2(r_1,\omega)d\omega &\leq \frac{C}{r_1}\int_{\tilde{\Sigma}_\tau\cap\{r\geq r_1\}}J_\mu^N[\psi]n^\mu_{\tilde{\Sigma}_\tau} = \frac{C}{r_1}\int_{\tilde{\Sigma}_\tau\cap\{r\geq r_1\}}\frac{D(\rho)}{D(\rho)}J_\mu^N[\psi]n^\mu_{\tilde{\Sigma}_\tau}\\ &\leq \frac{C}{r_1D(r_1)}\int_{\tilde{\Sigma}_\tau\cap\{r\geq r_1\}}D(\rho)J_\mu^N[\psi]n^\mu_{\tilde{\Sigma}_\tau}\\ &\leq \frac{C}{(r_1-M)^2}\int_{\tilde{\Sigma}_\tau}J_\mu^T[\psi]n^\mu_{\tilde{\Sigma}_\tau} \leq \frac{C}{(r_1-M)^2}\frac{E_1}{\tau^2}.\end{aligned}$$

□

Lemma 6.2.2. *There exists a constant C which depends only on M, R_1 such that for all $r_0 \in [M, R_1]$, $\alpha > 0$ and solutions ψ of the wave equation, we have*

$$\int_{\mathbb{S}^2}\psi^2(r_0,\omega)d\omega \leq CE_1\frac{1}{\tau^{2-2\alpha}} + C\sqrt{E_1}\frac{1}{\tau}\sqrt{\int_{\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq r_0+\tau^{-\alpha}\}}(\partial_\rho\psi)^2}.$$

Proof. We consider the hypersurface $\gamma_\alpha = \{r = r_0 + \tau^{-\alpha}\}$.



Then by applying Stokes' theorem for the hypersurfaces shown in the figure above we obtain

$$\int_{\mathbb{S}^2} \psi^2(r_0,\omega) \leq \int_{\mathbb{S}^2} \psi^2(r_0+\tau^{-\alpha},\omega) + C\int_{\tilde{\Sigma}_\tau \cap \{r_0 \leq r \leq r_0+\tau^{-\alpha}\}} \psi(\partial_\rho\psi).$$

For the first term on the right hand side we apply Lemma 6.2.1 (note that $M < r_0 + \tau^{-\alpha}$). The lemma now follows from Cauchy-Schwarz applied for the second term, the first Hardy inequality of [1] and Theorem 3. □

The case $l = 0$

We first assume that ψ is spherically symmetric. Then we have the pointwise bound

$$|\partial_\rho\psi| \leq C\sqrt{\tilde{E}_6},$$

in $\{M \leq r \leq R_1\}$, where

$$\tilde{E}_6 = \|\partial_r\psi\|^2_{L^\infty(\tilde{\Sigma}_0)} + E_4[\psi] + E_4[T\psi].$$

This can be easily proved by using the method of characteristics and integrating along the characteristic $u = c$ the wave equation (expressed in null coordinates). Hence Lemma 6.2.2 for $\alpha = \frac{2}{5}$ gives

$$\int_{\mathbb{S}^2} \psi^2(r_0,\omega)d\omega \leq CE_1\frac{1}{\tau^{\frac{6}{5}}} + C\sqrt{E_1}\sqrt{\tilde{E}_6}\frac{1}{\tau^{\frac{6}{5}}} \leq CE_6\frac{1}{\tau^{\frac{6}{5}}},$$

where $E_6 = E_1 + \tilde{E}_6$. Since ψ is spherically symmetric we obtain

$$\psi^2 \leq CE_6\frac{1}{\tau^{\frac{6}{5}}}. \tag{6.3}$$

The case $l = 1$

Suppose that ψ is supported on $l = 1$. Then from Lemma 6.2.2 for $\alpha = \frac{1}{4}$ we obtain

$$\begin{aligned}\int_{\mathbb{S}^2} \psi^2(r_0,\omega)d\omega &\leq CE_1\frac{1}{\tau^{\frac{3}{2}}} + C\sqrt{E_1}\frac{1}{\tau}\sqrt{\int_{\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq r_0+\tau^{-\alpha}\}}(\partial_\rho\psi)^2} \\ &\leq CE_1\frac{1}{\tau^{\frac{3}{2}}} + C\sqrt{E_1}\sqrt{E_2}\frac{1}{\tau^{\frac{3}{2}}} \leq C\tilde{E}_7\frac{1}{\tau^{\frac{3}{2}}}\end{aligned}$$

where we have used Proposition 5.5.1 and $\tilde{E}_7 = E_1 + E_2$. Therefore, by the Sobolev inequality on $\mathbb{S}^2$ we have

$$\psi^2 \leq CE_7\frac{1}{\tau^{\frac{3}{2}}}$$

in $\{M \leq r \leq R_1\}$, where $E_7 = \sum_{|k|\leq 2}\tilde{E}_7\left[\Omega^k\psi\right]$.

The case $l \geq 2$

Suppose that ψ is supported on $l \geq 2$. Then from (6.1) and Theorem 5.5.2 we have that there exists a constant C which depends only on M and R_1 such that

$$\int_{\mathbb{S}^2} \psi^2 \leq CE_3\frac{1}{\tau^2}$$

in $\{M\leq r\leq R_1\}$. By Sobolev we finally obtain

$$\psi^2\leq CE_8\frac{1}{\tau^2},$$

where $E_8=\sum_{|k|\leq 2}E_3\left[\Omega^k\psi\right]$. This completes the proof of Theorem 4.

6.3. **Applications.**

We next derive improved decay for the waves $T\psi$, $TT\psi$.

Proposition 6.3.1. *Fix R_1 such that $M<R_1$ and let $\tau\geq 1$. Let E_7,E_8 be the quantities as defined in Section 6.2. Then there exists a constant C that depends on M,R_1 and $\tilde{\Sigma}_0$ such that:*

- *For all solutions ψ to the wave equation we have*
$$|T\psi|\leq C\sqrt{E_7[T\psi]}\frac{1}{\tau^{\frac{3}{4}}},\quad |TT\psi|\leq C\sqrt{E_8[TT\psi]}\frac{1}{\tau},$$
in $\{M\leq r\leq R_1\}$.
- *For all solutions ψ to the wave equation which are supported on the frequencies $l\geq 1$ we have*
$$|T\psi|\leq C\sqrt{E_8[T\psi]}\frac{1}{\tau},$$
in $\{M\leq r\leq R_1\}$.

Proof. We first observe that Proposition 5.2.1 holds for all frequencies when ψ is replaced with $T\psi$. Indeed, we have shown that we can commute in this case with ∂_r (see Theorem 2, statement (2)). Therefore, using the third Hardy inequality of [1] implies that (5.8) and Proposition 5.5.1 hold for all frequencies when ψ is replaced with $T\psi$. Hence, the argument of Section 6.2.2 for the case $l=1$ works for all frequencies when restricted for $T\psi$.

Similarly, Proposition 5.2.2 holds for all frequencies when ψ is replaced with $TT\psi$ and so we can argue as in the case $l\geq 2$ above. The second part of the proposition follows in a similar way.

□

7. HIGHER ORDER ESTIMATES

We finish this paper by obtaining energy and pointwise results for all the derivatives of ψ. We first derive decay for the local higher order (non-degenerate) energy of high frequencies and then pointwise decay, non-decay and blow-up results for generic solutions. We finally use a contradiction argument to obtain blow-up results for the local higher order energy of low frequencies. The general form of Theorems 5, 6 of Section 2 is proved at the end of this section.

7.1. **Decay of Higher Order Energy.**

Theorem 7.1. *Fix R_1 such that $R_1>M$ and let $\tau\geq 1$. Let also $k,l\in\mathbb{N}$. Then there exists a constant C which depend on M,l,R_1 and $\tilde{\Sigma}_0$ such that the following holds: For all solutions ψ of the wave equation which are supported on the angular frequencies greater or equal to l, there exist norms $\tilde{E}_{k,l}$ of the initial data of ψ such that*

- $\displaystyle\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}}J^N_\mu[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq C\tilde{E}^2_{k,l}\frac{1}{\tau^2}$ *for all $k\leq l-2$,*
- $\displaystyle\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}}J^N_\mu[\partial_r^{l-1}\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq C\tilde{E}^2_{l-1,l}\frac{1}{\tau}.$

Proof. By commuting with T and applying local elliptic estimates and previous decay results, the above integrals decay on $\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq R_1\}$ where $r_0>M$. So it suffices to prove the above result for $\tilde{\Sigma}_\tau\cap\mathcal{A}$, where $\mathcal{A}$ is a φ_τ^T-invariant neighbourhood of $\mathcal{H}^+$. For we use the spacetime bound given by Theorem 2 which implies that there exists a dyadic sequence τ_n such that for all $k\leq l-1$ we have

$$\int_{\tilde{\Sigma}_{\tau_n}\cap\mathcal{A}}J^N_\mu[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_{\tau_n}}\leq CK_l\frac{1}{\tau_n},\tag{7.1}$$

where

$$K_l=\sum_{i=0}^{l}\int_{\tilde{\Sigma}_0}J_\mu^N\left[T^i\psi\right]n^\mu_{\tilde{\Sigma}_0}+\sum_{i=1}^{l}\int_{\tilde{\Sigma}_0\cap\mathcal{A}}J_\mu^N\left[\partial_r^i\psi\right]n^\mu_{\tilde{\Sigma}_0}.$$

Then, by Theorem 2 again we have for any τ such that $\tau_n\leq\tau\leq\tau_{n+1}$

$$\int_{\tilde{\Sigma}_\tau\cap\mathcal{A}}J_\mu^N[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_\tau}\leq C\sum_{i=0}^{k}\int_{\tilde{\Sigma}_{\tau_n}}J_\mu^N\left[T^i\psi\right]n^\mu_{\tilde{\Sigma}_{\tau_n}}+C\sum_{i=1}^{k}\int_{\tilde{\Sigma}_{\tau_n}\cap\mathcal{A}}J_\mu^N\left[\partial_r^i\psi\right]n^\mu_{\tilde{\Sigma}_{\tau_n}}\leq CE\frac{1}{\tau_n}\lesssim CE\frac{1}{\tau},$$

where E depends only on the initial data. Suppose now that $k\leq l-2$. We apply Theorem 2 for the dyadic intervals $[\tau_n,\tau_{n-1}]$ and we obtain

$$\int_{\mathcal{A}}J_\mu^N[\partial_r^k\psi]n^\mu_{\Sigma}\leq C\sum_{i=0}^{l-1}\int_{\tilde{\Sigma}_{\tau_{n-1}}}J_\mu^N\left[T^i\psi\right]n^\mu_{\tilde{\Sigma}_{\tau_{n-1}}}+\sum_{i=1}^{l-1}\int_{\tilde{\Sigma}_{\tau_{n-1}}\cap\mathcal{A}}J_\mu^N\left[\partial_r^i\psi\right]n^\mu_{\tilde{\Sigma}_{\tau_{n-1}}}.$$

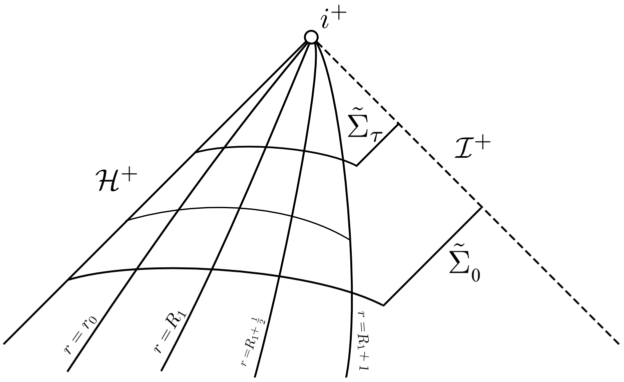
However, the right hand side has been shown to decay like τ^{-1} and thus a similar argument as above gives us the improved decay for all $k\leq l-2$. □

7.2. **Higher Order Pointwise Estimates.** The next theorem provides pointwise results for the derivatives transversal to $\mathcal{H}^+$ of ψ.

Theorem 7.2. *Fix R_1 such that $R_1>M$ and let $\tau\geq1$. Let also $k,l,m\in\mathbb{N}$. Then, there exist constants C which depend on M,l,R_1 and $\tilde{\Sigma}_0$ such that the following holds: For all solutions ψ of the wave equation which are supported on angular frequencies greater or equal to l, there exist norms $E_{k,l}$ of the initial data ψ such that*

- $\left|\partial_r^k\psi\right|\leq CE_{k,l}\dfrac{1}{\tau}$ *in* $\{M\leq r\leq R_1\}$ *for all* $k\leq l-2$,
- $\left|\partial_r^{l-1}\psi\right|\leq CE_{l-1,l}\dfrac{1}{\tau^{\frac{3}{4}}}$ *in* $\{M\leq r\leq R_1\}$,
- $\left|\partial_r^{l}\psi\right|\leq CE_{l,l}\dfrac{1}{\tau^{\frac{1}{4}}}$ *in* $\{M\leq r\leq R_1\}$.

Proof. Let r_0 such that $M\leq r_0\leq R_1$. We consider the cut-off $\delta:[M,R_1+1]\to[0,1]$ such that $\delta(r)=1,$ for $r\leq R_1+\frac{1}{4}$ and $\delta(r)=0,$ for $R_1+1/2\leq r\leq R_1+1$.



Then,

$$\begin{aligned}\int_{\mathbb{S}^2}\left(\partial_r^k\psi\right)^2(r_0,\omega)d\omega&=-2\int_{\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq R_1+1\}}\left(\partial_r^k(\delta\psi)\right)\left(\partial_\rho\partial_r^k(\delta\psi)\right)\\&\leq2\left(\int_{\tilde{\Sigma}_\tau\cap\{r\leq R_1+1\}}\left(\partial_r^k(\delta\psi)\right)^2\right)^{\frac{1}{2}}\left(\int_{\tilde{\Sigma}_\tau\cap\{r\leq R_1+1\}}\left(\partial_\rho\partial_r^k(\delta\psi)\right)^2\right)^{\frac{1}{2}}.\end{aligned}$$

In view of Theorem 7.1 if $k\leq l-2$ then both integrals on the right hand side decay like τ^{-2}. If $k=l-1$ then the first integral decays like τ^{-2} and the second like τ^{-1} and if $k=l$ the first integral decays like τ^{-1} and the second is bounded (Theorem 2). Commuting with the angular momentum operators and using the Sobolev inequality yield the required pointwise estimates for $\partial_r^k\psi$ for $k\leq l$. □

One can in fact show that $\partial_r^l\psi$ decays like $\tau^{-\frac{1}{4}-\delta_l}$, where $\delta_l>0$ by using the argument of Section 6 for the case $l=0$, i.e. by proving that $\partial_r^{l+1}\psi$ is uniformly bounded (note that we can not obtain $\frac{3}{5}$ decay in view of the fact that we can not use the first Hardy inequality, which allowed us to obtain further decay for the zeroth order term ψ in the previous section). We leave the details to the reader.

Let now $H_l[\psi]$ be the function on $\mathcal{H}^+$ as defined in Theorem 1. Since $H_l[\psi]$ is conserved along the null geodesics of $\mathcal{H}^+$ whenever ψ is supported on the angular frequency l, we can simply think of $H_l[\psi]$ as a function on $\mathbb{S}_0^2=\tilde{\Sigma}_0\cap\mathcal{H}^+$. We then have the following non-decay result.

Proposition 7.2.1. *For all solutions ψ supported on the angular frequency l we have*

$$\partial_r^{l+1}\psi(\tau,\theta,\phi)\to H_l[\psi](\theta,\phi)$$

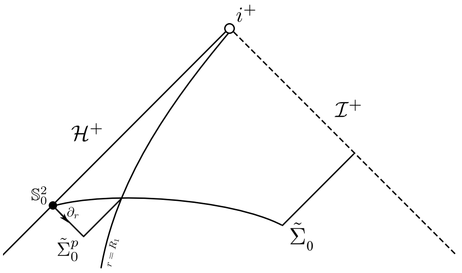
along $\mathcal{H}^+$ and generically $H_l[\psi](\theta,\phi)\neq 0$ almost everywhere on $\mathbb{S}_0^2$.

Proof. Since

$$\partial_r^{l+1}\psi(\tau,\theta,\phi)+\sum_{i=0}^{l}\beta_i\partial_r^i\psi(\tau,\theta,\phi)=H_l[\psi](\theta,\phi)$$

on $\mathcal{H}^+$ and since all the terms in the sum on the left hand side decay (see Theorem 7.2) we take $\partial_r^{l+1}\psi(\tau,\theta,\phi)\to H_l[\psi](\theta,\phi)$ on $\mathcal{H}^+$. It suffices to show that generically $H_l[\psi](\theta,\phi)\neq 0$ almost everywhere on $\mathbb{S}_0^2$. We will in fact show that for generic solutions ψ of the wave equation the function $H_l[\psi]$ is a generic eigenfunction of order l of $\Delta\!\!\!\!/$ on $\mathbb{S}_0^2$.

Note that the initial data prescribed on $\tilde{\Sigma}_0$ do not a priori determine the function $H_l[\psi]$ on $\mathbb{S}_0^2$ unless $l=0$. Indeed, $H_l[\psi]$ involves derivatives of order $k\leq l+1$ which are not tangential to $\tilde{\Sigma}_0$. For this reason we consider another Cauchy problem of the wave equation with initial data prescribed on $\tilde{\Sigma}_0^p$, where the hypersurface $\tilde{\Sigma}_0^p$ is as depicted below:



Note that the hypersurfaces $\tilde{\Sigma}_0$ and $\tilde{\Sigma}_0^p$ coincide for $r\geq R_1$. Any initial data set prescribed on $\tilde{\Sigma}_0$ gives rise to a unique initial data set of $\tilde{\Sigma}_0^p$ and vice versa. The Sobolev norms of the initial data on $\tilde{\Sigma}_0$ and $\tilde{\Sigma}_0^p$ can be compared using the pointwise and energy boundedness of [1]. Observe now that given initial data on $\tilde{\Sigma}_0^p$ the function $H_l[\psi]$ is completely determined on $\mathbb{S}_0^2$, since $H_l[\psi]$ involves only tangential to $\tilde{\Sigma}_0^p$ derivatives at $\mathbb{S}_0$. Therefore, generic initial data on $\tilde{\Sigma}_0^p$ give rise to generic eigenfunctions $H_l[\psi]$ of order l of $\Delta\!\!\!\!/$ on $\mathbb{S}_0$. Hence, for generic solutions ψ of the wave equation the functions $H_l[\psi]$ do not vanish almost everywhere on $\mathbb{S}_0$.

□

We next show that the above non-decay results imply that higher order derivatives of generic solutions ψ blow-up along $\mathcal{H}^+$. To make our argument clear we first consider the spherically symmetric case where $l=0$.

Proposition 7.2.2. *Let $k\in\mathbb{N}$ with $k\geq 2$. Then there exists a positive constant c which depends only on M such that for all spherically symmetric solutions ψ to the wave equation we have*

$$\left|\partial_r^k\psi\right|\geq c\left|H_0[\psi]\right|\tau^{k-1}$$

asymptotically on $\mathcal{H}^+$.

Proof. We work inductively. Consider the case $k=2$. By differentiating the wave equation (see for instance (3.5)) we take

$$2T\partial_r\partial_r\psi+\frac{2}{M}T\partial_r\psi-\frac{2}{M^2}T\psi+\frac{2}{M^2}\partial_r\psi=0 \tag{7.2}$$

on $\mathcal{H}^+$. Note that $T\partial_r^2\psi$ and $\partial_r\psi$ appear with the same sign. If $H_0[\psi]=0$ then there is nothing to prove. Let's suppose that $H_0>0$. Then

$$\int_0^\tau \partial_r\psi=\int_0^\tau H_0[\psi]-\frac{1}{M}\psi=H_0[\psi]\tau-\frac{1}{M}\int_0^\tau\psi.$$

We observe

$$\left|\int_0^\tau\psi\right|\leq\int_0^\tau|\psi|\leq CE_6\int_0^\tau\frac{1}{\tau^{\frac{3}{5}}}=CE_6\tau^{\frac{2}{5}}.$$

Therefore,

$$\int_0^\tau\partial_r\psi\geq H_0[\psi]\tau-CE_6\tau^{\frac{2}{5}}\geq cH_0[\psi]\tau$$

asymptotically on $\mathcal{H}^+$. By integrating (7.2) along $\mathcal{H}^+$ we obtain

$$\begin{aligned}\partial_r^2\psi(\tau)&=\partial_r^2\psi(0)+\frac{1}{M}\partial_r\psi(0)-\frac{1}{M}\partial_r\psi(\tau)-\frac{1}{M^2}\psi(0)+\frac{1}{M^2}\psi(\tau)-\frac{1}{2M^2}\int_0^\tau\partial_r\psi\\&\leq\partial_r^2\psi(0)+\frac{1}{M}\partial_r\psi(0)-\frac{1}{M}\left(H_0[\psi]+\frac{1}{M}\psi\right)-\frac{1}{M^2}\psi(0)+\frac{1}{M^2}\psi(\tau)-\frac{1}{2M^2}\int_0^\tau\partial_r\psi\\&\leq\partial_r^2\psi(0)+\frac{1}{M}\partial_r\psi(0)-\frac{1}{M}H_0[\psi]+CE_6\frac{1}{\tau^{\frac{3}{5}}}-cH_0[\psi]\tau\\&\leq -cH_0[\psi]\tau\end{aligned}$$

asymptotically on $\mathcal{H}^+$. A similar argument works for any $k\geq 2$. Indeed, we integrate (3.5) for $k\geq1$ (and $l=0$) along $\mathcal{H}^+$ and note that $T\partial_r^{k+1}\psi$ and $\partial_r^k\psi$ appear with the same sign. Therefore, by induction on k, the integral $\int_0^\tau\partial_r^k\psi$ dominates asymptotically all the remaining terms which yields the required blow-up rates on $\mathcal{H}^+$. Note that the sign of $\partial_r^k\psi$ depends on k and $H_0[\psi]$.

□

Corollary 7.2.1. *Let* $k\geq2$. *For generic initial data which give rise to solutions* ψ *of the wave equation we have*

$$\left|\partial_r^k\psi\right|\to+\infty$$

along $\mathcal{H}^+$.

Proof. Decompose $\psi=\psi_0+\psi_{\geq1}$ and thus

$$\int_{\mathbb{S}^2}\left|\partial_r^k\psi\right|^2(M,\omega)d\omega\geq4\pi\left|\partial_r^k\psi_0\right|^2(M,\omega).$$

Hence the result follows by commuting with Ω_i, the Sobolev inequality and the fact that the right hand side blows up as $\tau\to+\infty$ as $H_0[\psi]\neq0$ generically. □

Let us consider the case of a general angular frequency l.

Proposition 7.2.3. *Let* $k,l\in\mathbb{N}$ *with* $k\geq2$. *Then there exists a positive constant* c *which depends only on* M,l,k *such that for all solutions* ψ *to the wave equation which are supported on the frequency* l *we have*

$$\left|\partial_r^{l+k}\psi\right|(\tau,\theta,\phi)\geq c\left|H_l[\psi](\theta,\phi)\right|\tau^{k-1}$$

asymptotically on $\mathcal{H}^+$.

Proof. We first consider $k=2$. If $H_l[\psi](\theta,\phi)=0$ then there is nothing to prove. Suppose that $H_l[\psi](\theta,\phi)>0$. Note

$$\begin{aligned}\int_0^\tau \partial_r^{l+1}\psi &= H_l[\psi]\tau - \int_0^\tau \sum_{i=0}^{l}\beta_i\partial_r^i\psi\\ &\geq cH_l[\psi]\tau\end{aligned}$$

asymptotically on $\mathcal{H}^+$, since the integral on the right hand side is eventually dominated by $H_l[\psi]\tau$ in view of Theorem 7.2. If we integrate (3.5) (applied for $k=l+1$) along the null geodesic of $\mathcal{H}^+$ whose projection on the sphere is (θ,ϕ) we will obtain

$$\partial_r^{l+2}\psi(\tau,\theta,\phi)\leq -cH_l[\psi](\theta,\phi)\tau,$$

since the integral $\int_0^\tau \partial_r^{l+1}\psi$ eventually dominates all the remaining terms (again in view of the previous decay results). The proposition follows inductively by integrating (3.5) as in Proposition 7.2.2. Recall finally that for generic solutions ψ we have $H_l[\psi]\neq 0$ almost everywhere on $\mathbb{S}^2_0$.

□

7.3. **Blow-up of Higher Order Energy.** The next theorem provides blow-up results for the higher order non-degenerate energy. It also shows that our estimates in Section 7 are in fact sharp (regarding at least the restriction on the angular frequencies).

Theorem 7.3. *Fix R_1 such that $R_1>M$. Let also $k,l\in\mathbb{N}$. Then for generic solutions ψ of the wave equation which are supported on the (fixed) angular frequency l we have*

$$\int_{\tilde{\Sigma}_\tau\cap\{M\leq r\leq R_1\}} J_\mu^N[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_\tau}\longrightarrow +\infty$$

as $\tau\to+\infty$ for all $k\geq l+1$.

Proof. Consider $M<r_0<R_1$ and let δ be the cut-off introduced in the proof of Theorem 7.2. Then,

$$\begin{aligned}\int_{\mathbb{S}^2}\left(\partial_r^k\psi\right)^2(r_0,\omega)d\omega &= -2\int_{\mathbb{S}^2}\int_{r_0}^{R_1+1}(\partial_r^k(\delta\psi))(\partial_\rho\partial_r^k(\delta\psi))d\rho d\omega\\ &\leq C\int_{\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq R_1+1\}}\sum_{i=0}^{k}(T\partial_r^i\psi)^2+\sum_{i=0}^{k+1}(\partial_r^i\psi)^2,\end{aligned}$$

where C depends on M, R_1 and $\tilde{\Sigma}_0$. Then,

$$\begin{aligned}\int_{\mathbb{S}^2}\left(\partial_r^k\psi\right)^2(r_0,\omega)d\omega &\leq \frac{C}{D^{m_k}(r_0)}\int_{\tilde{\Sigma}_\tau\cap\{r_0\leq r\leq R_1+1\}}\sum_{i=0}^{k}J_\mu^T[T^i\psi]n^\mu_{\tilde{\Sigma}_\tau}\\ &\leq \frac{C}{(r_0-M)^{2m_k}}\left(\sum_{i=0}^{k}E_1(T^i\psi)\right)\frac{1}{\tau^2},\end{aligned}$$

where $m_k\in\mathbb{N}$. Note that for the above inequality we used local elliptic estimates (or a more pedestrian way is to use the wave equation and solve with respect to $\partial_r^k\psi$; this is something we can do since $D(r_0)>0$). Then using (3.5) we can inductively replace the ∂_r derivatives with the T derivatives. Therefore, commuting with Ω_i and applying the Sobolev inequality imply that for any $r_0>M$ we have $\left|\partial_r^k\psi\right|\to 0$ as $\tau\to+\infty$ along $r=r_0$. Let us assume now that the energy of $\partial_r^k\psi$ on $\tilde{\Sigma}_{\tau_j}\cap\{M\leq r\leq R_1\}$ is uniformly bounded by B (as $\tau_j\to+\infty$). Given $\epsilon>0$ take r_0 such that $r_0-M=\frac{\epsilon^2}{4Br_0^2}$ and let τ_ϵ be such that for all $\tau\geq\tau_\epsilon$ we have $\left|\partial_r^k\psi(\tau,r_0)\right|\leq\frac{\epsilon}{8\pi}$. Then,

$$\begin{aligned}\int_{\mathbb{S}^2}\left|\partial_r^k\psi(\tau_j,M)\right| &\leq \int_{\mathbb{S}^2}\left|\partial_r^k\psi(\tau_j,r_0)\right|+\int_{\tilde{\Sigma}_{\tau_j}\cap\{M\leq r\leq r_0\}}\left|\partial_\rho\partial_r^k\psi\right|\\ &\leq\frac{\epsilon}{2}+r_0(r_0-M)^{\frac{1}{2}}\left(\int_{\tilde{\Sigma}_{\tau_j}\cap\{M\leq r\leq R_1\}}J_\mu^N[\partial_r^k\psi]n^\mu_{\tilde{\Sigma}_{\tau_j}}\right)^{\frac{1}{2}}\leq\epsilon,\end{aligned}$$

for all $\tau \geq \tau_\epsilon$. This proves that $\int_{\mathbb{S}^2} \left|\partial_r^k \psi(\tau_j, M)\right| \to 0$ as $t_j \to +\infty$ along $\mathcal{H}^+$. However, in view of Propositions 7.2.1 and 7.2.3 we have

$$\int_{\mathbb{S}^2(M)} \left|\partial_r^k \psi\right|(\tau_j) \geq c\tau_j^{k-1} \int_{\mathbb{S}^2(M)} \left|H_l[\psi]\right|.$$

We have seen that for generic ψ the function $H_l[\psi]$ is non-zero almost everywhere and since it is smooth we have $\int_{\mathbb{S}^2(M)} |H_l[\psi]| > 0$. This shows that the integral $\int_{\mathbb{S}^2} \left|\partial_r^k \psi(\tau_j, M)\right|$ can not decay, contradiction. □

7.4. **Applications.** We conclude this paper by proving Theorem 5 and 6 of Section 2 which provide the complete picture for the derivatives of ψ.

Proof of Theorem 5. The first two statements can be proved as the Proposition 7.1 by observing that in view of statement (2) of Theorem 2 we can find a dyadic sequence τ_n such that (7.1) holds for all $k \leq l + m - 1$. Having proved these two statements, the remaining ones can be proved by repeating the argument of Theorem 7.2. □

Proof of Theorem 6. The first statement follows from Proposition 3.1.1 and the previous decay results. For the second statement we integrate (3.5) for $k = l + m + 1$ and ψ replaced with $T^{m-1}\psi$ and observe that $\int_0^\tau \partial_r^{l+m+1} T^m \psi$ dominates eventually all the remaining terms. However, in view of statement (1) we have $\int_0^\tau \partial_r^{l+m+1} T^m \psi \sim cH_j[\psi]\tau$ which completes the proof for $k = l + m + 2$. The general case can be proved by induction on k. Finally, the above two statements imply that generically the integral $\int_{\mathbb{S}^2} \left|\partial_r^k T^m \psi(\tau, \theta, \phi)\right|$ can not decay as $\tau \to +\infty$ along $\mathcal{H}^+$. Therefore, the last statement can be proved by repeating the argument of Theorem 7.3.

□

8. Acknowledgements

I would like to thank Mihalis Dafermos for introducing to me the problem and for his teaching and advice. I also thank Igor Rodnianski for sharing useful insights. I am very grateful to an anonymous referee who carefully read this work and suggested many improvements and corrections. I am supported by a Bodossaki Grant.

Appendix A. Elliptic Estimates on Lorentzian Manifolds

Let us suppose that $(\mathcal{M}, g)$ is a globally hyperbolic time-orientable Lorentzian manifold which admits a Killing vector field T. We also suppose that $\mathcal{M}$ is foliated by spacelike hypersurfaces Σ_τ, where $\Sigma_\tau = \phi_\tau(\Sigma_0)$. Here, Σ_0 is a Cauchy hypersurface and ϕ_τ is the flow of T.

Let N be a ϕ_τ-invariant **timelike** vector field and constants B_1, B_2 such that

$$0 < B_1 < -g(N,N) < B_2.$$

We will first derive the required estimate in Σ_0 which for simplicity we denote by Σ. For each point $p \in \Sigma$ the orthogonal complement in $T_p\mathcal{M}$ of the line that contains N is 3-dimensional and contains a 2-dimensional subspace of the tangent space $T_p\Sigma$. Let X_2, X_3 be an orthonormal basis of this subspace. Let now X_1 be a vector tangent to Σ which is perpendicular to the plane that is spanned by X_2, X_3. Note that the line that passes through X_1 is uniquely determined by N and Σ. Then, the metric g can be written as

$$g = \begin{pmatrix} g_{NN} & g_{NX_1} & 0 & 0 \\ g_{NX_1} & g_{X_1X_1} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad g^{-1} = \begin{pmatrix} \frac{1}{|g|} g_{X_1X_1} & -\frac{1}{|g|} g_{NX_1} & 0 & 0 \\ -\frac{1}{|g|} g_{NX_1} & \frac{1}{|g|} g_{NN} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

with respect to the frame (N, X_1, X_2, X_3) and $|g| = g_{NN} \cdot g_{X_1X_1} - g_{NX_1}^2$. Let h_Σ be the induced Riemannian metric on the spacelike hypersurface Σ. Clearly, in general we do **not** have $h_\Sigma^{ij} = g^{ij}$.

Indeed

$$h_{\Sigma}=\begin{pmatrix} g_{X_1X_1} & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix},\quad h_{\Sigma}^{-1}=\begin{pmatrix} \frac{1}{g_{X_1X_1}} & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix}.$$

Let $\psi:\mathcal{M}\rightarrow\mathbb{R}$ satisfy the wave equation. Then,

$$\Box_g\psi=\operatorname{tr}_g\left(\operatorname{Hess}\psi\right)=g^{\alpha\beta}\left(\nabla^2\psi\right)_{\alpha\beta}=g^{0\beta}\Big(\left(\nabla^2\psi\right)_{0\beta}+\left(\nabla^2\psi\right)_{\beta 0}\Big)+g^{ij}\left(\nabla^2\psi\right)_{ij}.$$

We will prove that the operator

$$P\psi=g^{ij}\left(\nabla^2\psi\right)_{ij}$$

is strictly elliptic. Indeed, in view of the formula $\left(\nabla^2\psi\right)_{ij}=X_iX_j\psi-\left(\nabla_{X_i}X_j\right)\psi$, the principal part σ of P is

$$\sigma\psi=g^{ij}X_iX_j\psi.$$

If $\xi\in T^*\Sigma$, then

$$\sigma\xi=g^{ij}\xi_i\xi_j=\frac{1}{|g|}g_{NN}\xi_1^2+\xi_2^2+\xi_3^3>b\left(\frac{1}{g_{X_1X_1}}\xi_1^2+\xi_2^2+\xi_3^3\right)=b\left\|\xi\right\|,$$

where the ellipticity constant $b>0$ depends only on Σ. Moreover, if ψ satisfies $\Box_g\psi=0$ then

$$\begin{aligned}\left\|P\psi\right\|^2_{L^2(\Sigma)}=&\left\|g^{0\beta}\Big(\left(\nabla^2\psi\right)_{0\beta}+\left(\nabla^2\psi\right)_{\beta 0}\Big)\right\|^2_{L^2(\Sigma)}\\ \leq& C\int_{\Sigma}\left(\left\|NN\psi\right\|^2_{L^2(\Sigma)}+\sum_{i=1}^{3}\left\|X_iN\psi\right\|^2_{L^2(\Sigma)}+\sum_{i=1}^{3}\left\|X_i\psi\right\|^2_{L^2(\Sigma)}+\left\|N\psi\right\|^2_{L^2(\Sigma)}\right)\\ \leq& C\int_{\Sigma}J_{\mu}^{N}[\psi]n^{\mu}_{\Sigma}+J_{\mu}^{N}[N\psi]n^{\mu}_{\Sigma},\end{aligned}$$

where C is a uniform constant that depends only on the geometry of Σ and the precise choice of N. Therefore, if ψ can be shown to appropriately decay at infinity then by a global elliptic estimate on Σ we obtain

$$\left\|\psi\right\|^2_{\dot{H}^1(\Sigma)}+\left\|\psi\right\|^2_{\dot{H}^2(\Sigma)}\leq C\cdot\left\|P\psi\right\|^2_{L^2(\Sigma)}\leq\int_{\Sigma}CJ_{\mu}^{N}[\psi]n^{\mu}_{\Sigma}+CJ_{\mu}^{N}[N\psi]n^{\mu}_{\Sigma}.$$

for some uniform positive constant C (here $\dot{H}^k\left(\Sigma\right)$ denotes the homogeneous Sobolev space where the zeroth order term is omitted).

In case our analysis is local and thus we want to confine ourselves in a compact submanifold $\overline{\Sigma}$ of Σ then by a local elliptic estimate on $\overline{\Sigma}$ we have

$$\left\|\psi\right\|^2_{H^2(\overline{\Sigma})}\leq C\cdot\left\|P\psi\right\|^2_{L^2(\overline{\Sigma})}+\left\|\psi\right\|^2_{H^1(\overline{\Sigma})}\leq\int_{\overline{\Sigma}}\Big(CJ_{\mu}^{N}[\psi]n^{\mu}_{\overline{\Sigma}}+CJ_{\mu}^{N}[N\psi]n^{\mu}_{\overline{\Sigma}}+\psi^2\Big).$$

One can also estimate spacetime integrals by using elliptic estimates. Indeed, if $\overline{\mathcal{R}}\left(0,\tau\right)$ is the spacetime region as defined before, then

$$\int_{\overline{\mathcal{R}}(0,\tau)}f\left|\nabla u\right|dg_{\overline{\mathcal{R}}}=\int_0^{\tau}\left(\int_{\overline{\Sigma}_{\tau}}fdg_{\overline{\Sigma}_{\tau}}\right)dt,$$

where the integrals are with respect to the induced volume form and $u:\mathcal{M}\rightarrow\mathbb{R}$ is such that $u\left(p\right)=\tau$ iff $p\in\overline{\Sigma}_{\tau}$. Then ∇u is proportional to $n_{\overline{\Sigma}_{\tau}}$ and since $T(u)=1$, ∇u is ϕ_{τ}-invariant. Therefore, $\left|\nabla u\right|$ is uniformly bounded. If now f is quadratic on the 2-jet of ψ then

$$\begin{aligned}\left|\int_{\overline{\mathcal{R}}(0,\tau)}fdg_{\overline{\mathcal{R}}}\right|&\leq C\int_0^{\tau}\left\|\psi\right\|^2_{H^2\left(\overline{\Sigma}_{\tilde{\tau}}\right)}d\tilde{\tau}\leq C\int_0^{\tau}\left(\int_{\overline{\Sigma}_{\tilde{\tau}}}J_{\mu}^{N}[\psi]n^{\mu}_{\overline{\Sigma}_{\tilde{\tau}}}+J_{\mu}^{N}[N\psi]n^{\mu}_{\overline{\Sigma}_{\tilde{\tau}}}+\psi^2\right)d\tilde{\tau}\\ &\leq C\int_{\overline{\mathcal{R}}(0,\tau)}J_{\mu}^{N}[\psi]n^{\mu}_{\overline{\Sigma}}+CJ_{\mu}^{N}[N\psi]n^{\mu}_{\overline{\Sigma}}+\psi^2.\end{aligned}$$

In applications we usually use these results away from $\mathcal{H}^+$ where we commute with T and we use the degenerate X and Morawetz estimates of [1]. We can also use this estimate even if Σ (and $\mathcal{R}$) crosses $\mathcal{H}^+$, provided we have commuted the wave equation with N and NN (recall that we need commutation with NN only for degenerate black holes).
